A plan for municipal irrigation from the Los Angeles aqueduct, B. A. HEINLY (*Engin. News*, 73 (1915), No. 7, pp. 344-346, fig. 1).—It is stated in this article that the surplus waters of the Los Angeles aqueduct are to be distributed by a number of main conduits and a vast network of smaller pipe to irrigate 87,000 acres.

The soil of the district to be irrigated ranges from sandy loam to clay, and much of it is said to be adapted to the growth of citrus fruits.

In this system there will be 317 miles of riveted steel mains from 8 to 54 in. in diameter under a head of from 40 to 300 ft. Storage reservoirs will also form a part of the system. The estimated cost of the entire project is \$4,472,674, or \$50.90 per acre. Of the latter, \$17.42 will be borne by the city and \$33.58 by the owners of the land to be irrigated.

The Valier-Montana irrigation project, K. A. HERON (*Engin. News*, 73 (1915), No. 6, pp. 241-246, figs. 12).—A description is given of what is said to be the largest Carey Act project in Montana. Important features of this project are a rock fill dam 165 ft. high forming a large reservoir, a larger storage reservoir formed by a less important dam, and 153 miles of main and 274 miles of distributing laterals on which are structures, including concrete chutes, pipe lines, and drops, to reduce high velocities.

Thirteenth annual report of the Reclamation Service, 1913-14 (*Ann. Rpt. Reclamation Serv.* [U. S.], 13 (1914), pp. V+505).—This report relates in particular to the work completed and in progress during the fiscal year ended June 30, 1914, but contains also information in regard to previous operations, "in order that the methods, progress, and results of reclamation work may be more readily understood."

Notes in connection with the work in the hydrographic department of the Porto Rico Irrigation Service, F. K. KNAPP (*Cornell Civ. Engin.*, 23 (1915), No. 5, pp. 195-206).—"These notes are based upon the Porto Rican Irrigation Service records of observations in connection with the actual routine field work prior to operation, and are comments upon some special problems arising from unusual conditions rather than discussion of hydrographic investigations."

Irrigation in Spain, G. F. DE LA ROSA (*Bol. Agr. Téc. y Econ.*, 6 (1914), No. 67, pp. 620-622; *abs. in Internat. Inst. Agr.* [Rome], *Mo. Bul. Agr. Intel. and Plant Diseases*, 5 (1914), No. 11, pp. 1420, 1421).—The total irrigated area in

Spain is estimated at 3,233,108 acres, of which about 200,000 acres are irrigated with subsoil water. Two-thirds of the area is distributed in the four great districts of Spain as follows: Aragon and Navarre, 580,091 acres; Catalonia, 472,920 acres; Levante, 629,259 acres, and the Boetic-Mediterranean region, 361,690 acres.

Three systems of irrigation are practiced, namely, pumping from wells, canals fed by the large rivers, and artificial lakes or reservoirs, the third being preferred. The use of artesian water has not been very successful.

Report of the interstate conference on artesian water (*Rpt. Interstate Conf. Artesian Water [Aust.], 1912, pp. XV+275, pls. 42*).—This report covers the origin, extent, and use of artesian water in Australia, hydrographic surveys, boring and casing of artesian wells, and legislation for controlling artesian bores, and devotes considerable space to the corrosion of well casings.

Ownership and disposal of seepage water, J. G. WHITEHEAD (*Irrig. Age, 30 (1915), No. 4, pp. 104, 105, fig. 1*).—The subject is discussed from the standpoints of both the landowner whose land is seeped and the landowner whose land needs irrigation, it being concluded "that the ownership and control of seepage water is now, and should be, in the landowner on whose land it is."

Malaria control: Drainage as an antimalarial measure, J. A. A. LE PRINCE (*Pub. Health Rpts. [U. S.], 30 (1915), No. 8, pp. 536-545, figs. 13*).—The author discusses land drainage as an antimosquito measure, with particular reference to training natural streams and water courses, construction of open and intercepting ditches, installation of permanent lining in ditches, subsurface draining, filling, and proper maintenance. He points out that the ordinary methods of draining agricultural land are not sufficient for mosquito control, and states that land must not only be properly drained, but the drainage ditches must be so planned, constructed, and maintained that they will not become a breeding place for mosquitoes. "As a general rule shallow water is more favorable to mosquito production than deep water. A depth of an inch is sufficient; therefore, in order to prevent mosquito breeding we must remove all the water or make conditions unfavorable."

The agricultural utilization of the water of municipal sewage, R. PEROTTI (*Bol. Quind. Soc. Agr. Ital., 19 (1914), No. 22, pp. 801-810*).—The author discusses the possibilities in the agricultural use of municipal sewage, both for irrigation and fertilizing purposes. He points out, however, the importance of making such a process successful from the standpoints of both agriculture and sewage purification and disposal. He suggests, therefore, that it be a Government undertaking.

Disposal of sewage from hospitals and medical establishments, H. KÜHL (*Heilanstalt, 8 (1913), No. 2, pp. 21-23; abs. in Wasser u. Abwasser, 9 (1915), No. 2, p. 37*).—The best process for the purification of such sewage is said to be by land irrigation. Where the necessary land is unavailable a biological sewage purification system is considered necessary. A number of such systems are described.

Fifth biennial report of the state highway commissioner, F. F. ROGERS (*Bien. Rpt. State Highway Comr. Mich., 5 (1913-14), pp. 123, pls. 34, figs. 9*).—This is a report of the activities of the commissioner during the biennium ended with June, 1914. Considerable structural data are included.

Results of French experiments on the transmission of pressure through macadam to the subgrade, W. DE H. WASHINGTON (*Engin. and Contract., 42 (1914), No. 25, p. 571*).—French tests on the amount of pressure exerted through

the road on the subgrade by a wheel load of 4 tons, with a 5½-in. tire, gave the following results:

Transmission of pressure through macadam to subgrade.

Macadam alone.		Foundation alone.		Combined foundation and macadam.			
Crust thickness.	Pressure on subsoil per square inch.	Founda-tion thickness.	Pressure on subsoil per square inch.	Founda-tion thickness.	Pressure on subsoil per sq. in.		
					Macadam thickness 3.94 in.	Macadam thickness 5.91 in.	Macadam thickness 7.87 in.
<i>Inches.</i>	<i>Pounds.</i>	<i>Inches.</i>	<i>Pounds.</i>	<i>Inches.</i>	<i>Pounds.</i>	<i>Pounds.</i>	<i>Pounds.</i>
1.97	102.5	5.91	56.0	5.91	19.3	13.2	9.7
3.94	47.7	7.81	37.4	7.87	14.7	10.9	8.2
5.91	27.4	11.81	20.7	9.84	12.6	9.1	6.8
7.87	17.4	11.81	10.2	7.7	6.1
11.81	9.1

The pressure on the subsoil through a 12-in. bed of simple macadam is apparently the same as the pressure through a 6-in. bed of macadam laid over a 10-in. stone foundation. It is considered that poor soil requires at least a 12-in. macadam layer or its equivalent.

Test of a bridge slab, E. B. McCORMICK (*Cement Era*, 13 (1915), No. 3, pp. 54, 55, figs. 8).—The author briefly describes experiments being conducted by the Office of Public Roads and Rural Engineering of this Department to determine the effective width of reinforced concrete bridge and culvert slabs under various conditions of loading. The effective width is considered to be “the width of a slab, which, if subjected to a load of a certain magnitude, uniformly distributed along the top fiber of the center section, will have the same maximum outside fiber stress, and the same total fiber stress as the tested slab showed under the concentrated load of that magnitude.”

Diagrams are given showing lines of equal stress and fiber stresses along sections for a slab under one, two, and four point loadings. The diagrams for center loads show that the effective width is the same for loads of different magnitude, that is, “the effective width of a slab is apparently independent of the magnitude of the load.”

No conclusions are drawn, as further investigations are in progress.

Estimating curves for standard bridges of the Illinois Highway Department, G. F. BURCH (*Engin. and Contract.*, 43 (1915), No. 6, pp. 123–126, figs. 13).—This article gives data and a set of curves for estimating the quantities of materials in the various types of highway bridges designed by the Illinois Highway Department.

Structural engineering, J. E. KIRKHAM (*Chicago: The Myron C. Clark Publishing Co.*, 1914, pp. V+669, pls. 3, figs. 452).—This book, while dealing primarily with general structural engineering, contains a section covering the design of simple steel highway bridges, including the beam, pony truss, and high truss types.

Tests and uses of hydrated lime, R. C. HAFF (*Cement Era*, 13 (1915), No. 2, p. 69).—The author found in his tests that the addition of from 10 to 15 per cent of hydrated lime to 1:3 cement and sand mortar increased the strength. He states that his experience has proved hydrated lime to be the best waterproofing material available, and recommends the addition of 15 per cent for this purpose.

The industrial use of peat, E. C. VERSCHOOR (*Chem. Weekbl.*, 11 (1914), No. 45, pp. 980-990).—This article discusses the use of peat as a fuel for steam boilers and as a source of gas fuel for gas burners and internal combustion engines. The heat efficiency obtained from the gas is said to be greater than from the fuel itself. The development of gas fuel from peat is thought, therefore, to offer the greater commercial inducement.

The use of electricity on Ontario farms, H. P. STARRETT (*U. S. Dept. Com., Com. Rpts.*, No. 52 (1915), pp. 886-888).—It is stated that since the action taken in 1905 whereby the province controls and operates all water powers within its boundaries, the use of electricity on farms has gradually developed and "the result today in Ontario is the definite establishment of electricity as a very practical aid to the farmer of the more progressive type. In this development actual experiments have demonstrated that motors developing from 1 to 8 horsepower will do all of the ordinary power work of the farm, while for the heavier work, such as threshing, silo filling, grinding, etc., 20-horsepower motors are required."

It is stated that considerable economy has accompanied the use of electric current as compared with steam.

Machines and implements at the 1914 exposition of the German Agricultural Society, LUEDECKE (*Fühling's Landw. Ztg.*, 63 (1914), No. 19-20, pp. 609-654, figs. 22).—This article describes and illustrates recent developments in a large number of agricultural machines.

The first large American Humphrey pump, C. C. TRUMP (*Gas Engine*, 17 (1915), No. 2, pp. 95-100, figs. 8).—This article describes and illustrates a 66-in. pump to be used for irrigation purposes, said to be the first of its kind in this country. The principles under which this type of pump operates were described in a previous article (*E. S. R.*, 26, p. 893).

A new deep-well pump, L. ANDREUZZI (*Agr. Colon. [Italy]*, 7 (1914), No. 10, pp. 620-640, pls. 2, figs. 6).—The author describes and diagrammatically illustrates a type of compressed-air or pneumatic pump which he states is adapted to deep-well pumping for both irrigation and domestic uses. The mathematical principles underlying the operation of this pump are presented and efficiency tests compared with similar tests of other types of pumps, particularly the centrifugal pump. It is claimed that an efficiency of 70 per cent may be exceeded with this pump, while the tests of other types show efficiencies rarely reaching 70 per cent. Its deep-well pumping facilities are said to be its greatest asset.

Results of a tractor investigation, P. S. ROSE (*Amer. Thresherman*, 17 (1915), No. 11, pp. 5-9, fig. 1).—The author tabulates the first 96 answers to a large number of letters sent to tractor owners in the various States and the western provinces of Canada asking for views as to tractor farming.

A large percentage of the replies stated that the tractor is cheaper than horses. The estimates of service ranged from 4 to 25 years, with an average of a little less than 10 years. While some of the repair bills have been rather high, it is stated that the amount of work has been in proportion and the cost per unit of work has been excessive only in a few cases. It is also brought out that no particular make of tractor has had a monopoly of either the successes or the failures. Of the 60 per cent reporting the possession of a shop, a number have been unsuccessful with the tractor.

The author states that on the whole the evidence that he has obtained is favorable to the tractor, in spite of the number of failures, which he attributes mostly to lack of knowledge on the part of the operator in the beginning.

The gas tractor situation in Iowa, J. B. DAVIDSON (*Amer. Thresherman*, 17 (1915), No. 11, pp. 70, 71, fig. 1).—The author states that the factors which will

influence the success of the gas tractor in the State are the character of the farming, the size and topography of the farms, the climate, the prosperity of the farmer, and the present extensive use of machinery. He is of the opinion that out of 225,000 farms in Iowa 50,000 could use the tractor with economic success.

The tractor situation in Indiana, A. H. GILBERT (*Amer. Thresherman*, 17 (1915), No. 11, pp. 10, 11, fig. 1).—Of 36 replies received from tractor users in the State, 30 reported the tractor to be a practical investment, 2 said that it paid fairly well, and 3 reported a failure. The author maintains that while the present situation does not prove conclusively that the tractor is a profitable investment for every farm, it can be made a paying proposition in Indiana.

Small tractor a benefit to Kansas threshermen, R. C. NICHOL (*Amer. Thresherman*, 17 (1915), No. 11, pp. 74, 75, fig. 1).—The author is of the opinion that threshermen will be benefited materially from the present interest in small tractors due to the increased yields brought about by the use of mechanical power.

The Minnesota view of traction engines, J. L. MOWRY (*Amer. Thresherman*, 17 (1915), No. 11, pp. 18, 19, fig. 1).—In reviewing the tractor situation in the State, the author states that the traction engine has not been a paying investment in the past, and he is of the opinion that a 240-acre farm is the smallest that can profitably use a traction engine.

The necessary and most appropriate machines for the tillage of different classes of soil, A. R. URANGA (*Bol. Estac. Agr. Expt. San Juan Bautista, Tabasco*, No. 9, (1913), pp. 40, figs. 61).—This bulletin describes and illustrates a number of the more common tillage tools and other agricultural implements.

Note on machines for pseudocultivation, M. RINGELMANN (*Ann. Inst. Nat. Agron.*, 2. ser., 13 (1914), No. 1, pp. 5-31, figs. 10).—The author reviews a number of dynamometer tests of scarifiers, weeders, cultivators, and disk pulverisers in soils of different density.

The results show that these machines, which the author terms pseudocultivators, require a tractive effort per unit section of moved earth which is equal to, and in some cases greater than, the tractive effort required per unit section of moved earth for a double bottom plow in the same soil. They also show the influence of the density of the soil on the required tractive effort for these machines. With a soil density of 1.99, the average traction in kilograms per square decimeter was for the scarifiers 45.5, weeders 72, cultivators with flexible teeth 25.8, and pulverizer 31.8. The corresponding values with a soil density of 2.03 were 47.9, 74.1, 42.9, and 50.3.

It is stated that when these machines are operated on a soil which does not support vegetation these results should be multiplied by a coefficient varying according to the nature and state of the soil from 0.7 to 0.8.

With reference to a proposal that the pseudocultivators be used several times in place of one passage of the deeper tilling plow, it is concluded that it is more practicable to use the plow. It is further concluded that on the same work under the same conditions less energy is expended on machines with flexible teeth or shovels than with rigid shovels. The tests also show that the flexible shovels should be fixed in groups of three to five on independent frames and not on one rigid frame.

Construction of sanitary mangers in dairy barn at Troy, Pa. (*Concrete-Cement Age*, 6 (1915), No. 2, pp. 104-106, figs. 8).—This article illustrates and describes the method of construction of a large L-shaped dairy barn, 70 by 102 ft. in plan, wherein sanitary mangers have been installed.

The housing of the agricultural laborer, H. D. SEARLES-WOOD (*Jour. Roy. Sanit. Inst.*, 36 (1915), No. 1, pp. 29-37, figs. 2).—The author discusses various

plans which have been put forward for the housing of agricultural laborers in England, and gives information regarding arrangement and construction, including plans.

Cottage building in rural districts, T. W. POTTER (*Jour. Roy. Sanit. Inst.*, 36 (1915), No. 1, pp. 38-44).—The author expresses his views regarding the housing requirements in rural districts, which he states have been developed from 25 years' experience, chiefly on large estates.

Dampness in houses, its cause and remedy, M. METZGER (*Deut. Landw. Presse*, 41 (1914), Nos. 98, pp. 1015, 1016; 100, p. 1032).—This article draws attention to the unhealthful conditions caused by dampness in houses, and points out the effectiveness of waterproofing and insulating cellar walls in preventing the entrance and capillary rise of ground water.

RURAL ECONOMICS.

The resources of United States and their relation to opportunity, R. M. KEIR (*Ann. Amer. Acad. Polit. and Soc. Sci.*, 59 (1915), No. 148, pp. 1-28, figs. 36).—The author points out that the natural resources as related to population are high in the United States compared with other countries, but that if the resources do not increase as rapidly as the population the opportunities decrease accordingly. He claims that up to the year 1892 the exports from the United States were chiefly farm products. Since that time the percentage of agricultural exports to the total has rapidly declined, while manufactured goods ready for consumption have comprised a larger and larger proportion, and one which is increasing more rapidly than the increase in population. With a corresponding falling off in farm exports it follows that greater numbers of men are working in factories. He believes that the country should, therefore, pay more attention to conserving the wealth it has, and should make increased efforts to gain foreign trade. He also advises that the United States seek to sell manufactured goods and keep more raw materials at home.

The open door to independence, T. E. HILL (*Chicago: Hill Standard Book Co.*, 1915, pp. 448, pl. 1, figs. 413).—This book describes the natural and agricultural resources of the various States and gives details regarding government irrigation projects and other general information of interest to those who wish to engage in agriculture.

Farms for sale or rent in New York, C. W. LARMON (*N. Y. Dept. Agr. Bul.* 67 (1915), pp. 641-974, pls. 49).—This bulletin lists the farms for sale or for rent in New York, and briefly describes them.

Farm land for sale in West Virginia (*W. Va. Dept. Agr. Bul.* 2 (1915), pp. 117, figs. 15).—This publication lists and describes the farms for sale in West Virginia.

The efficiency movement in its relation to agriculture, W. J. SPILLMAN (*Ann. Amer. Acad. Polit. and Soc. Sci.*, 59 (1915), No. 148, pp. 65-76).—The author points out a number of typical instances where an analysis of a farmer's business has shown wherein lay the weakness in his system of management.

Diversified agriculture and the relation of the banker to the farmer, B. KNAPP (*U. S. Dept. Agr., Off. Sec. Circ.* 50 (1915), pp. 15).—In this address, delivered to several State bankers' associations and the Southern Commercial Congress, the author points out that a system of agriculture for any given community ought to be self-supporting and to have sufficient diversification so that its interests are not jeopardized by mishaps to one crop. To bring this about he suggests the establishment of local cash markets for locally grown produce, and that the credit system should be so changed that the farmer would adopt a plan

of farming which would make his farm self-supporting. Bankers and merchants should, in his opinion, alter their present system of giving credit upon the basis of the farmer devoting a certain acreage to a single crop to the requirement that the farmer establish a diversified system.

Rural cooperation in the sandhill section of North Carolina, R. A. DERBY (*Market World and Chron.*, n. ser., 9 (1915), No. 20, pp. 630-632).—There is in this community a federated board of trade composed of the local boards of the 17 towns in the league. This article describes the methods employed by the federated board in developing the agricultural interest of the community by means of exhibits, a better school system, and the establishment of marketing and warehouse facilities.

Cooperation and the great war, G. R. CARTER (*Cooperation Agr.* [London], 11 (1915), No. 5, pp. 77-83).—The author of this article believes that the greater the degree of self-sufficiency possessed by cooperative industrial societies through the resources of wholesale societies, the more stable the position of the cooperator as a consumer. The strength of the latter is apparent if he is able to draw upon the resources of the farmer, the manufacturer, the banker, and the commercial agent entirely through the cooperative connections of his society.

The Muscovite Union of cooperative distributive societies and rural distributive cooperation in Russia (*Internat. Inst. Agr.* [Rome], *Mo. Bul. Econ. and Soc. Intl.*, 6 (1915), No. 4, pp. 16-34).—According to the author, of the total number of distributive societies in Russia on January 1, 1912, 4,716, or 70.1 per cent, could be classified as rural cooperative distributing societies. Between 1865 and 1912, 7,626 societies had been established, one-eighth of which had been dissolved. The functions of the societies are classified under the following heads: (1) Commercial, where the union seeks to concentrate in its hands the capital and orders of the separate cooperative societies, to effect purchases in common on the best and cheapest conditions possible, and to eliminate useless intermediaries between producers and purchasers; (2) production, where the union proposes, by opening cooperative workshops and factories, to encourage production by its members, and to organize sales in such a way as to prevent as far as possible purchases independent of it; and (3) non-economic, where the union seeks to diffuse the idea of cooperation and the knowledge required for the practical realization of this idea.

The author also discusses the development of these societies and the amount of business transacted.

Suggested lines of cooperative production, W. W. THOMSON (*Saskatchewan Dept. Agr. Cooper. Organ. Branch Bul.* 42 (1914), pp. 24, figs. 2).—This bulletin describes the essentials for successful organization of community breeding associations, seed-growing centers, cooperative egg circles, and beef rings, and gives suggested constitutions and by-laws.

Cooperative live stock marketing, W. W. THOMSON (*Saskatchewan Dept. Agr. Cooper. Organ. Branch Bul.* 41 (1914), pp. 30).—The author outlines the advantages of cooperative marketing associations and points out methods of organization and operating. This bulletin also contains a suggested constitution and by-laws, forms used in accounting, and a brief description of markets for Saskatchewan live stock.

Studies in the marketing of farm products, L. D. H. WELD (*Univ. Minn. Studies Soc. Sci.*, No. 4 (1915), pp. 113, pls. 2, figs. 14).—This publication contains a series of articles concerning the following subjects: Market Distribution, by L. D. H. Weld (*E. S. R.*, 33, p. 293); The Marketing of Live-Stock Products in Minnesota, by K. F. Warner; Cooperative Potato Marketing in Minnesota.

by O. B. Jesness; *The Marketing of Minnesota Poultry*, by S. H. Thompson; *Milk Distribution in Minneapolis and St. Paul*, by W. L. Cavert; *Minneapolis Central City Market*, by R. M. Peterson; and *Cooperative Marketing of Grain in Western Canada*, and *the Food Supply of the Iron Range*, by L. D. H. Weld.

The permanent warehouse and marketing law (*33. Tex. Leg., 2. Sess., House Bill 4 (1914)*, pp. 77).—The text of this law, together with a number of forms for use in carrying it out is given.

[Elevators in western Canada] (*Saskatchewan Dept. Agr. Bul. 35 (1913)*, pp. 21-25).—It is pointed out that there were 516 elevators and grain-storage warehouses in Saskatchewan in 1907, with a capacity of 14,621,500 bu. of grain. By 1912 the number had increased to 1,252, and the capacity to 36,503,000 bu. Detailed data as to the various elevators are included.

Cost of farm implements (*Saskatchewan Dept. Agr., Ann. Rpt. Sec. Statis., 7 (1913)*, pp. 11-15).—Following an investigation regarding the cost and methods of purchasing farm implements, it is recommended that no salesman of any implement company shall canvass farmers for farm implements except within the limits of cities, towns, and villages. Waivers of exemption rights in purchase contracts should be considered null and void. The security of implement companies should be limited to the article sold and to the individual liability of the purchaser. Interest on all notes in respect to farm machinery should be limited to 8 per cent. All contracts for the sale of farm implements should be entered into before a notary public or justice of the peace, who should explain the terms of the contract to the purchaser. No mortgage should be given in respect to farm implements for a sum less than \$300.

Statistical abstract for the British Empire in each year from 1899 to 1913 (*Statis. Abs. Brit. Empire, 11 (1899-1913)*, pp. XII+306).—Among the statistical data contained in this report are the quantity of agricultural products imported and exported, with the country of origin and destination, the total quantity produced, and the total and per capita consumption.

Prices and supplies of grain, live stock, and other agricultural produce in Scotland (*Agr. Statis. Scotland, 2 (1913)*, pt. 3, pp. 189-241, figs. 3).—This report gives prices and supplies of grain, live stock, and other agricultural produce at the principal markets and in different counties in Scotland for 1913, with comparative data for earlier years.

The agriculture of Lund and Helleland, Norway, H. AARSTAD (*Tidsskr. Norske Landbr., No. 4 (1915)*, Bilag, pp. 46, figs. 4).—The author describes the climate, topography, character of the soil, and the area used for different agricultural purposes.

Agriculture in the Lower Alps, M. CAPODURO (*L'Agriculture dans les Basses-Alpes. Paris: J. B. Baillièrè and Sons, 1914*, pp. 120, figs. 3).—This monograph describes the soil, topography, climate, flora, and fauna, the occupation and movement of the population, types of crops grown, and the general agricultural practice.

Emigration from Roman Tuscany, G. VALENSIN (*Atti R. Accad. Econ. Agr. Georg. Firenze, 5. ser., 11 (1914)*, No. 3, pp. 264-281).—The author discusses the agricultural conditions by districts, and the extent of the emigration and its destination.

American influence upon the agriculture of Hokkaido, Japan (*Sapporo, Japan: Tohoku Imp. Univ., 1915*, pp. 21, pls. 11).—This report indicates the agricultural machines and implements, field and horticultural crops, and live stock introduced into the island from America and their influence upon its agriculture.

AGRICULTURAL EDUCATION.

The training in forestry during the next decade, J. W. TOUMÉY (*Off. Pubs. Cornell Univ.*, 5 (1914), No. 19, pp. 27-35).—The author submits a brief survey of the origin and development of forestry education in this country, and points out some of its weaknesses and needs.

He finds that the "tremendous impetus in national and state forestry coincident with the development of the older forestry schools of collegiate grade, and their inability to supply at once all the men required by the national and state governments and for private work, stimulated to an inordinate degree the development of facilities for forestry education and the multiplication of schools" until the United States now has 21 colleges and universities that offer degrees in forestry and announce that they train men for the broad fields of national, state, and private forestry. Of the collegiate institutions 18 at the close of 4 years of satisfactory work offer the degree of B. S. in forestry and one the degree of forest engineer; 6 institutions at the close of an additional year of graduate work offer the degree of master of forestry or of master of science in forestry; in 2 institutions the work is wholly of graduate character, the degree of master of forestry being given for 2 years of satisfactory work. "After less than 15 years of development in forestry education in the United States, we have more schools that aim to prepare men for the profession of forestry than there are in all Europe after more than a century of forest school development."

In the opinion of the author the inclination has been to overemphasize empirical methods and to underemphasize fundamental laws and efficiency. Forestry education should be developed by incorporating forestry in the general education system of the country from the public school to the university as a coordinate subject with agriculture or horticulture, and by the development of ranger schools which should teach merely the art or trade of forestry. The rational development of the educational system along these lines will make it necessary for the high-grade professional man at the top to be better trained and surer of his technical equipment, minor subjects will be cut out of the curricula of professional schools, greater emphasis placed on fundamental subjects, and greater specialization undertaken on the professional side.

Development of instruction in animal and dairy husbandry, H. NYLANDER (*Kreatursskötsel- och Mejerilärlings-Institutionens Utveckling. Helsingfors: Govt.*, 1914, pp. 53).—The author discusses the development of practical instruction in animal and dairy husbandry, in accordance with the provisions of the law of 1908, the text of which is included, for the reorganization of this instruction.

Agricultural education (*Ber. Deut. Sect. Landesk. Rates Königr. Böhmen*, 22 (1913), pp. 21-71).—A detailed report on the activities of itinerant agricultural instructors, and progress notes on agricultural schools and educational institutions in 1913 under the supervision of the German Section of the Agricultural Council of Bohemia.

Agricultural schools and itinerant instruction (*Jahresber. Landw. Kammer Prov. Sachsen*, 1912, pp. 125-133).—This is a report on the agricultural and housekeeping schools, special courses, agricultural instruction in the army, and itinerant agricultural instruction under the supervision of the chamber of agriculture of the Province of Saxony in Prussia.

Agricultural education service (*Jaarb. Dept. Landb., Nijv. en Handel Nederland. Indië*, 1913, pp. 79-186, pls. 9).—A report on the activities of the department of agriculture in promoting agricultural instruction in 1913 in the Dutch East Indies,

A historical sketch of the College of Agriculture, Tohoku Imperial University (*Sapporo, Japan, 1915, pp. 22, pls. 12*).—This sketch indicates what American educators have done to assist in the founding and development of the College of Agriculture at Sapporo, Japan, including its founding in 1876 by William S. Clark, then president of the Massachusetts Agricultural College.

Does an agricultural education pay? C. H. LANE (*High School Quart. [Ga.], 3 (1915), No. 3, pp. 203-205*).—The author calls attention to the results of several studies relating to the incomes of farmers with varying degrees of education.

How to teach agriculture, C. W. BURKETT, F. L. STEVENS, and D. H. HILL (*Boston: Ginn and Co., 1914, rev. ed., pp. 22*).—This is a revision of the text issued in 1906, in which the authors offer suggestions on what to teach, what not to teach, and how to teach, including the conduct of experiments, and a suggested outline of lesson topics based on Agriculture for Beginners (E. S. R., 16, p. 832).

Agriculture for the Kansas common schools, L. E. CALL and H. L. KENT (*Topeka, Kans.: State, 1914, pp. V+468, pls. 4, figs. 483*).—The subject matter of this text was prepared by the staff of the Kansas College and Station, but was rearranged for uniformity and better adaptation to the needs of the schools. It consists of lessons on the structure and growth of plants, grain crops, marketing and milling wheat, legumes, grasses, improvement of plants and animals, weeds, soils, drainage, irrigation, feeding and raising farm animals, dairying, poultry, diseases of animals and plants, growing and caring for trees, insects, spraying, orcharding, the vegetable garden, beautifying home grounds, birds, and good roads. Each chapter is followed by review questions and an appendix contains suggestions on method of teaching, list of reference books, directions for making the Babcock test and measuring farm products and land, a seed table for field crops adapted to Kansas, etc.

Agriculture, theoretical and practical, J. WRIGHTSON and J. C. NEWSHAM (*London: Crosby Lockwood and Son, 1915, pp. XX+628, figs. 322*).—This textbook of mixed farming, for large and small farmers and agricultural students, comprises six parts treating of (1) soils, manures, and crops; (2) live stock, feeding, and economic zoology; (3) buildings, machinery, implements, and accounts; (4) dairying; (5) horticulture; and (6) poultry, rabbits, and bees.

Agriculture and life, A. D. CROMWELL, edited by K. C. DAVIS (*Philadelphia: J. B. Lippincott Co., 1915, pp. X+369, pl. 1, figs. 143*).—This text was written for normal training classes and teachers' reading circles to give instruction in methods of teaching agriculture in the common schools. Following the discussion of educational aims in which the author calls attention to the educational, economic, esthetic, moral, and religious values of agriculture, chapters are devoted to seed selection and plant breeding; pets and home projects; stock and grain judging; feeds and feeding; farm accounts and farm management; the soil; school and home gardens; birds and agriculture; insects and agriculture; plant and animal diseases; weeds; rural life institutions; the rural school, festivals, clubs, short courses, and continuation schools; and courses of study, correlations, booklets, lesson plans, tables, etc. Each topic is followed by review questions and references to the literature.

Simple laboratory exercises for high schools, M. C. CROSS (*Rural Educator, 4 (1914), No. 4, pp. 65, 66; 5 (1915), No. 1, pp. 13, 14*).—The author outlines 25 simple laboratory exercises in plants, animals, farm management and machinery, soils, and plant growth, largely adapted from standard texts and bulletins.

Studies in soils, M. J. ABBEY (*W. Va. School Agr., 5 (1915), No. 7, pp. 23, figs. 11*).—The author outlines lessons in soil formation, activities, and improvement.

Experiments with living plants, M. OETTLI (*Versuche mit lebenden Pflanzen*. Leipzig: B. G. Teubner, 1914, pp. 44, figs. 7).—The author outlines experiments in plant constituents, food, germination, and growth for pupils from 12 to 14 years old and offers suggestions for keeping a notebook.

A forestry arithmetic for Vermont schools, A. F. HAWES (*Vt. Forestry Pub. 14* (1914), pp. 30, pls. 4).—Examples in forestry arithmetic to supplement the text-book are given, together with simple experiments to learn tree flowers and seeds, to study seed distribution and germination, the growth of trees, and the rotting of wood, and to teach how to make observations at the sawmill.

Insects of economic importance, G. W. HERRICK (*Ithaca, N. Y.: Carpenter and Co., 1915, pp. 138*).—These outlines of lectures in economic entomology discuss the habits and life histories of the principal pests of the main fruits, vegetables, cereals, farm animals, and shade trees, methods of control, losses caused by insects in this country, and the cost of combating insects. References to literature are added.

[Farm animals], M. J. ABBEY (*W. Va. School Agr., 5* (1914), No. 4, pp. 24, figs. 9; *5* (1915), No. 5, pp. 22, figs. 11).—The first of these papers deals with winter care, and outlines lessons in housing, feeding, and caring for animals, with suggestions for correlation with other subjects. The second presents lessons on types of horses, sheep, and hogs, including data on judging contests and farm arithmetic.

Domestic science, BERTHA J. AUSTIN (*Chicago: Lyons and Carnahan, vols. 1* [1914], pp. 192, figs. 79; *2* (1914), pp. 239, figs. 60; *3* (1915), pp. 334, figs. 91).—The subject matter of this course of practical training in cookery is pedagogically presented, the steps in every process being given in the order of operation and the underlying principles clearly set forth. The first two volumes, designed for the first and second years of the course, take up the cooking necessary for the average menu for the three daily meals, while the third volume, for the third and fourth years, is devoted to more advanced subjects, such as the preservation of food, including canning, preserving, jelly making and pickling, the chemistry of foods, food values, studies in dietetics and invalid cookery, the cost of living, business in the household, household accounts, and some practical problems in food arithmetic.

Supplementary problems for domestic science classes (*Manila: Bur. Ed., 1913, pp. 49*).—These arithmetic problems relating to domestic science have been prescribed as supplementary exercises for the sixth and seventh grades.

Household arts (*Missouri Bd. Agr. Mo. Bul., 13* (1915), No. 2, pp. 88, figs. 50).—This bulletin furnishes an outline for school work in domestic arts, including the various stitches and their practical application, pattern drafting, selection of materials, suggestions for making garments, public exhibitions and score cards, etc.

The house and its furnishing, ABBIE DELURY (*Univ. Saskatchewan, Col. Agr. Bul. 4* (1914), pp. 31, figs. 15).—The different parts of the house are considered as to plan and furnishing.

Home laundering, TREVA E. KAUFFMAN (*Agr. Col. Ext. Bul. [Ohio State Univ.], 10* (1915), No. 7, pp. 16, figs. 14).—The author offers practical suggestions on equipment for laundering, fabrics, effects of alkalis and acids on fabrics, cleaning and bleaching agents, removal of stains, and washing operations.

Arbor and Bird Day manual (*W. Va. School Agr., 5* (1915), No. 6, pp. 79, figs. 31).—This manual comprises outlines for the study of trees and birds, by M. J. Abbey, and a description of 40 common birds of West Virginia, together with brief accounts of their range, habits, and usefulness, by E. A. Brooks.

Ohio arbor and bird annual, F. W. MILLER (*Ohio Dept. Pub. Instr. Bul. 6* (1915), pp. 96, figs. 67).—A compilation of articles and poems on trees and birds.

NOTES.

Alabama College.—The first degree of doctor of science to be conferred by the institution has been granted to A. L. Quaintance of the Bureau of Entomology of this Department.

California University and Station.—*Science* announces that plans are being prepared for an additional building of the agricultural group to cost \$250,000; the first unit of a new group of chemistry buildings, this structure to cost \$250,000; and the completion of the university library at a cost of \$400,000.

A marble chair is about to be placed in the open-air Greek theater in honor of Dr. E. W. Hilgard, professor of agriculture and dean of the college of agriculture from 1875 to 1906 and now professor emeritus. The degree of emeritus professor of horticulture has been conferred upon ex-Dean Wickson.

Idaho University and Station.—Recent appointments include Carl B. Wilson as director of the school of practical agriculture and instructor in agricultural education; C. V. Singleton as instructor and assistant in animal husbandry; and Glen S. Ray as assistant in farm crops.

Illinois University.—H. W. Stewart has resigned to become assistant professor of soils at the University of Wisconsin. W. J. Fraser and John W. Lloyd have been granted leave of absence for further study, the former in rural economics at Harvard University and the latter at the University of California.

Nebraska University.—The contract has been let for the new dairy building. A structure 141 by 64 feet is planned, with three stories and basement and a wing 70 by 30 feet especially arranged for handling butter, ice cream, and market milk. The first floor of the main building will contain student laboratories, the second a large milk testing laboratory, quarters for experimental work, a reading room, and offices, and the third, the dairy bacteriological laboratories, a large lecture room, and class rooms. A modern refrigerating plant in the basement will provide cold storage facilities for dairy work and also in horticulture, home economics, and veterinary science.

Third Conference of American Association of Agricultural College Editors.—This conference was held at the College of Agriculture, University of Wisconsin, June 24 and 25, with representatives and visitors from 19 institutions in 18 States and this Department.

An address of welcome was given by Dean H. L. Russell, who drew attention to the more specific division of labor in the agricultural colleges and experiment stations due to their growth and increasing complexity of organization. He stated that the editorial work, connected usually though not always directly with the administrative office of the institution, is coming to be one of its most important departments, although it is hard to find men who are fitted by both temperament and training to conduct it. In his opinion one of the most important things for the consideration of the association is the matter of the popularization of scientific material for the use of the farming community at large. Permanent bulletins, both scientific and popular, he regarded as necessary, but inasmuch as the farm paper is more widely read, many more people can be reached through that medium.

The presidential address by C. A. Whittle, of Georgia, had for its subject *The Status of the Agricultural College Editor*. In his opinion the mission of the agricultural college editor is to reach the individual farmer, and in order to render him adequate service the editor must see, feel, and think the same way. The greatest defect in editorial work at present was thought to be the limit of the power of the "blue pencil." He believed that editors must be vested with full editorial powers, but that when these powers are given they must be used wisely and very carefully. He also advocated conferring upon them full professorial rank.

Dr. B. E. Powell, of Illinois, in his report as secretary-treasurer reviewed the history of the organization. He called attention to the large demand for the proceedings of the last meeting, although these could not be published because of the lack of available funds. Subsequently provision was made by the association for the publication of the proceedings of the 1915 meeting.

G. W. Wharton, chief of the Office of Information of this Department, discussed *Getting Information to the People Who Can Use It*. He cited as obstacles to the successful dissemination of agricultural information, (1) overtechnical statements, (2) attempts to mix both popular and technical matter in the same bulletin, and (3) the tradition of form, size, type, etc. He advocated the use of posters, colors, cards, and general follow-up methods. He much preferred the term "information" instead of "publicity" in such work, as "publicity" has come to be associated with "press agency" with which a properly defined information service can have no connection. The most efficient medium for the dissemination of agricultural information he thought to be the farm press, and the next the daily and weekly newspapers. In any case those issuing information material must write from the viewpoint of both the editor and the farmer.

Mr. Wharton stated that while, of course, it was impossible to attribute the increase to any one specific cause, the circulation of the Department's bulletins since the establishment of the information service had, according to last year's figures, increased 40 per cent. Inasmuch as the press notices contain fairly complete summaries and practical advice, he believed that those who now write in for the bulletins as a result of these notices do so because of a real need, and it is probable, therefore, that the notices assist in reducing waste circulation. He described in detail the activities of the Office of Information, explaining especially the method of limiting the press material to the class of papers or the geographical district to which it would be of direct application. He believed that the press material should be deemed an official output of the institution as well as its bulletins or other permanent publications. It should concern itself merely with conveying practical information and recommendations and be kept scrupulously free from any partisan tinge. Mention of individuals or institutions should be limited to what is necessary to establish the authority of the facts or advice. One great advantage of mimeographed press information sheets, he pointed out, is that they can be issued in cases of emergency and through the cooperation of the press reach those affected far more quickly than ordinarily would be possible in the case of formal publications.

Frank C. Dean, of Nebraska, read a paper on *The Efficiency of Press Matter for Newspapers*, defining efficiency as the ability to get a thing published. He considered the preparation of press matter the most important of the agricultural college editor's duties. Items of ten lines or less have been found most useful for newspapers, and 95 per cent of the papers to whom he has furnished news material have used only about one column per week.

In a paper on *Some Common Inconsistencies of Typography of Bulletins*, O. M. Kile, of West Virginia, presented the tabulated replies from about 25 editors in

answer to a questionnaire on the usage of compound and hyphenated words and certain synonyms, and the capitalization of breed, variety, and certain other names, which showed a very wide variation in usage. A discussion followed on the use of style books and other standards. A committee on proper usage of compound words, forms, capitalization, etc., was appointed, consisting of O. M. Kile, B. Adams, and A. W. Hopkins, and a preliminary report of this committee, embodying numerous suggestions, was subsequently adopted.

Walter Stemmons, of the Oklahoma College, read a paper on How to Get Press Material from the Staff, in which he narrated some difficulties encountered. He has found one of the best helps toward getting material to be the occasional sending to members of the staff press clippings of material they have furnished. The field reports of county agents in the extension service have also been a fruitful source of stories of human interest.

Mr. Esborn, of the Simplified Spelling Board, addressed the association on simplified spelling. He reviewed the present movement for spelling reform and stated that up to May 15, 1915, 100 educational institutions in the United States and Canada and about 100 newspapers and periodicals with a combined circulation of over 2,000,000 had approved the movement.

T. R. Bryant discussed the use of placards, giving experiences in Kentucky for two or three years. Neat bulletin boards with glass fronts have been installed in the stations of five railroad systems in the State, the agents exchanging the placards monthly. The railroads have been very enthusiastic about this feature and the practice has appeared to be very effective.

Charles Dillon, of Topeka, Kans., addressed the meeting on the Source of News and What is News from a College of Agriculture. He discussed especially the press material being sent out by the agricultural colleges and experiment stations to farm papers and newspapers, illustrating by concrete examples some of its shortcomings from the viewpoints of the editor of the paper who is to publish the material and of the farmer who is to read it. He also exhibited advertising and publicity material of railroads and business houses. He closed his remarks by reading papers prepared by agricultural journal editors on What College Editors Ought to Send Out to Farm Papers. The sending out of advice which farmers can readily adopt and more reasonable matter were especially desired.

A round table discussion was opened by F. W. Beckman, of Iowa, on the question, Do College Editors in Sending Material to Newspapers Interfere with the Activities of Farm Papers? Some differences of opinion were noted in various States, but the advantage of utilizing the newspaper to create as much as possible an interest in farming was generally recognized.

In a discussion of the propriety of the receiving of compensation by a college editor for articles furnished papers, the consensus of opinion seemed to be adverse to the practice as regards papers within the State, with wider differences of opinion as regards other articles.

Another question discussed was the handling of requests from outside the State for publications. The use of classified mailing lists was mentioned as helpful in conserving editions. One of the chief functions of the agricultural college and station editor as regards the permanent and scientific publications of these institutions was suggested by M. D. Moore, of the States Relations Service of this Department, as that of so informing the farmers and others interested of the nature of these publications that intelligent request can be made for the publication wanted.

One session of the association was held at the Forest Products Laboratory, where an address was given by Director H. F. Weiss of the laboratory, on the types and prices of the different papers being used by the stations. Mr. Weiss

based his remarks on tests made in the laboratory of samples sent in by various editors. Wide differences in the cost and value of these samples were revealed by the comparison.

Bristow Adams, of Cornell University, presented a comprehensive discussion of An Information Service in Connection With Extension Work. He gave a detailed review of the evolution of the information work at Cornell University, where the attempt is now made to reach by means of reading courses, press service, etc., the farmer not yet in touch with the field man in extension work. In the matter of publications, direct and intimate relation is maintained between the bulletins, memoirs, etc., and press notices in extension work. Press notices are sent out about the bulletins, especially to the county or counties to which those of a local nature pertain, to fruit growers in the case of a bulletin pertaining to them, etc. Each notice emphasizes the fact that the complete bulletin can be had on application. The use of the term "publicity work" is deprecated, as misleading. The right kind of information service is regarded as that farthest removed from publicity and an advertising propaganda, which is its own undoing, whereas the service which seeks only to help the farmer will be permanent.

The program was concluded with an illustrated lecture by F. J. Trezise, of Chicago, on What is Required to Make a Typographically and Mechanically Good Bulletin. This was an instructive discussion from an expert point of view of such questions as measure balance, proportional margins, shape harmony, use of borders and decorated margins, tone harmony, and use of cuts, type, and harmony in border arrangements.

A special feature of the convention was the exhibit of bulletins and other illustrative material, contributed by 18 institutions and this Department. Information and press material preponderated in the exhibits, but several of the institutions, notably Wisconsin and Iowa, also illustrated the evolution of the regular bulletin in a striking way.

The constitution submitted by a special committee was adopted. Among the resolutions agreed to were those memorializing the Association of American Agricultural Colleges and Experiment Stations as to the desirability of further developing editorial work, establishing full editorial authority, and otherwise improving its status and dignity, favoring the use of the term "information service" in preference to that of "publicity," and suggesting the need of means for utilizing the publications of one institution by others.

Officers for the ensuing year were selected as follows: President, F. W. Beckman of Iowa; vice president, F. H. Jeter of North Carolina; secretary-treasurer, B. E. Powell of Illinois; and additional members of the executive committee, C. A. Whittle of Georgia, and N. A. Crawford of Kansas.

The executive committee is empowered under the new constitution to decide as to the place of the next annual meeting.

Vocational Agricultural Education in New York.—The regents of the University of the State of New York have voted to reorganize the present Vocational Schools Division into a Division of Agricultural and Industrial Education with A. D. Dean as director.

A recent act of the state legislature authorizes the board of supervisors of any county outside of the City of New York to establish a farm school for the purpose of giving instruction in the trades and in industrial, agricultural, and home making subjects to children of the county between the ages of eight and eighteen. Each of such schools may receive annually from the State \$1,000 and an additional \$200 for each teacher employed therein for a period of 36 weeks during each school year whose entire time is given to the instruction of pupils in the school, provided the school has at least 15 pupils actually in

attendance during the 36 weeks and its organization and course of study have been approved by the commissioner of education. The board of supervisors must provide for the maintenance of the school, the repair and improvement of the buildings, land, and the equipment.

Agricultural Advancement in the Caucasus.—In response to the increasing demand for assistance in agricultural research and education, the viceroy of the Caucasus appointed in 1913 a commission of the leading farmers and specialists to consider the more efficient correlation of the various agricultural agencies. Their report when submitted recommended the concentration of all educational, experimental, and extension work under the board of agriculture, with the establishment of agricultural stations at suitable points, the employment of district agriculturists, and a system of advisory work by government specialists.

A permanent commission was also suggested, with the chief of the agricultural section of the Caucasus as president and with representatives from the Tiflis Botanical Gardens, the Caucasian Sericultural Station, senior specialists of the board of agriculture, officials connected with the various land-improvement and educational services, members of the civil veterinary section, and the Imperial Agricultural Society of the Caucasus as members, the commission to be supplemented by the addition of district agriculturists, superintendents of agricultural establishments, other specialists, and in general of all persons competent in agricultural affairs, as desired. A reference section and statistical and editorial bureau were projected.

The early opening of the Tiflis Polytechnic Institute with an agricultural section, the establishment of schools for intermediate agricultural education, and the introduction of practical agriculture into the elementary school system, were also advocated. In 1913, about \$500,000 was expended for agricultural advancement in this region, of which \$35,000 was for agricultural organization, \$300,000 for experimental work, etc., \$10,000 for live stock improvement, \$25,000 for aid to agricultural societies, and \$20,000 for destruction of insects, exhibitions, meetings, collection of statistics, and other activities.

Miscellaneous.—The medal and grant for 1915 of the South African Association for the Advancement of Science have been awarded to C. P. Lounsbury, chief of the department of entomology of the Union Department of Agriculture.

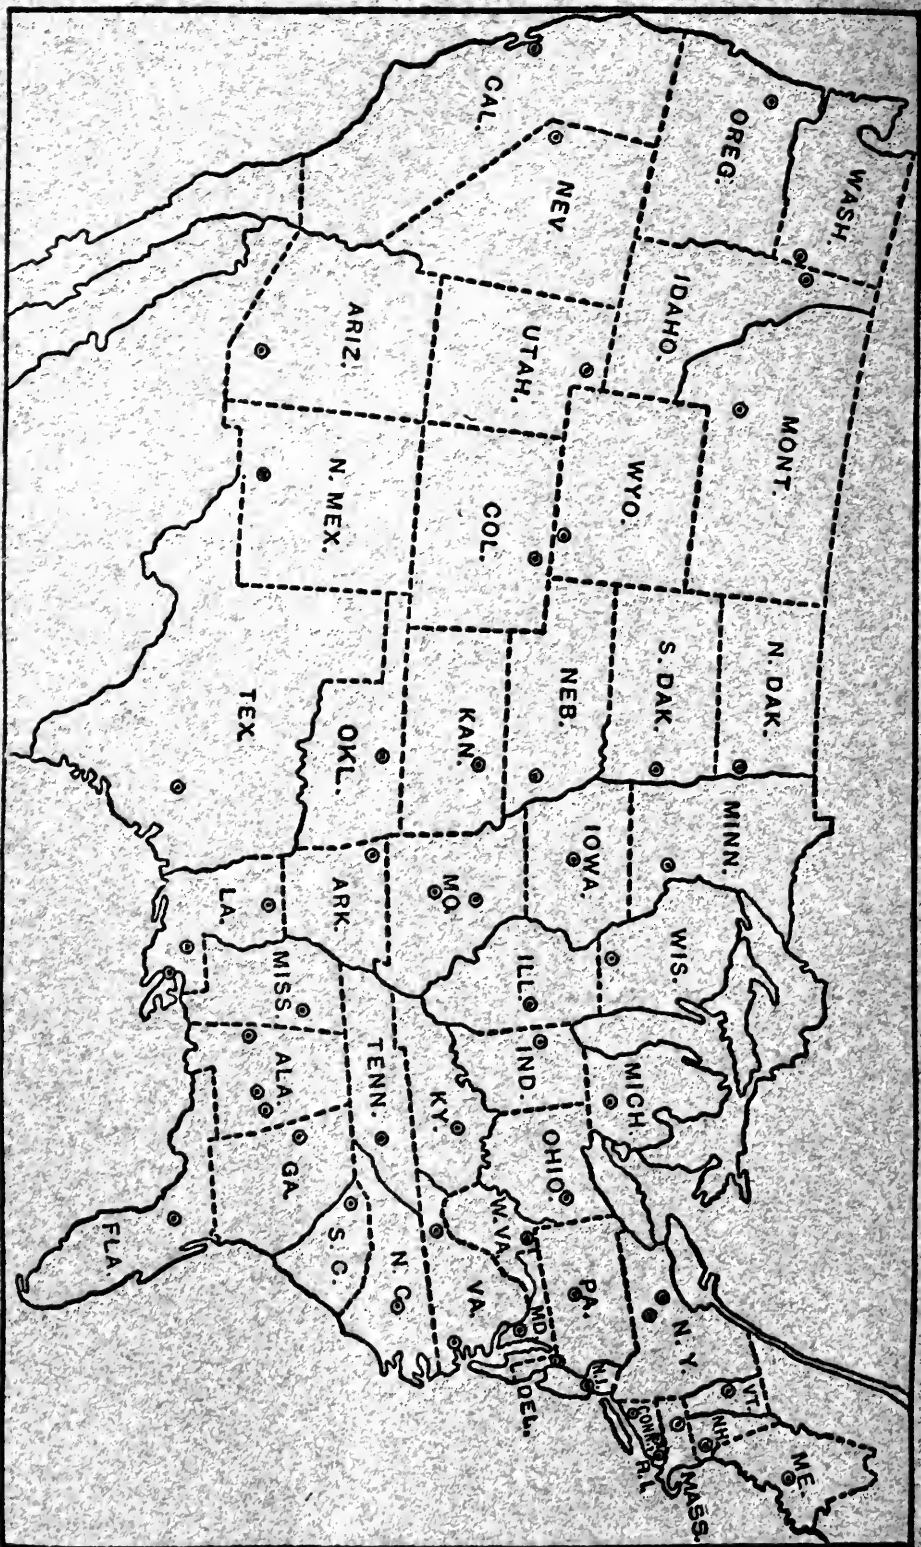

A new laboratory of plant pathology at Kew Botanic Gardens has been recently opened. A. D. Cotton has been promoted to assistant in connection with the new laboratory with W. B. Brierley as first class assistant.

Dr. A. W. Bothwick, lecturer in forest botany in the University of Edinburgh, has been appointed advisory officer for forestry to the Scottish Board of Agriculture, vice the late Dr. John Nisbet.

M. T. Dawe, director of agriculture in British East Africa, has been appointed agricultural adviser to the Government of Colombia.

SUBJECT LIST OF ABSTRACTS.

AGRICULTURAL CHEMISTRY—AGROTECHNY.

A rapid method of estimating nitrates, Knecht.....	501
The estimation of protein ammonia, Wiukler.....	501
Oxidation of carbohydrates by potassium persulphate, Wood and Walker.....	502
Analytical work, Gile and Carrero.....	502
Determination of eggs in food pastes, Farcy.....	502
The ferments of honey, Gothe.....	502
Experimental studies on honey diastase activity, Gothe.....	502
Estimation of chlorin ions in honey, Nottbohm.....	502
Preservation of milk samples for examination purposes, Tillmans et al.....	502
Changes in milk preserved with potassium bichromate, Kling et al.....	503
The action of milk mold on phenylaminoacetic acid, Forsters.....	503
Volumetric estimation of casein in milk by aid of tetraserum, Pfyl and Turnau.....	503
Old and new methods for determining fat in milk, Oven.....	503
Determination of lactose in milk by the polarimetric method, Feder.....	503
Estimation of viscosity of milk as an aid for detecting added water, Kooper.....	504
Detection of goat's milk in cow's milk, Pritzker.....	504
The freezing point of some abnormal milks, Henderson and Meston.....	504
The electrical conductivity of milk during its concentration, Jackson et al.....	504
Dry milk with particular reference to determining the fat content, Utz.....	505
Césaro's method for the detection of coconut fat in butter, Stœclin.....	505

	Page.
Rapid analysis of butter: Estimation of noufats, Isnard.....	505
Extraction of neutral fats from ripe sheep's milk cheese, Bárány.....	505
Determination of unsaponifiable matter in oils and fats, Salomon.....	506
Rice oil and rice fat, Davidsohn.....	506
Estimation of hydrocyanic acid in feeding stuffs and its occurrence, Furlong..	506
Solvents employed in the determination of hop-bitter constituents, Seibriger..	507
Method for quantitative determination of resins in hops, Winge and Jensen....	507
Employment of artificial light in titration of the resins in hops, Larsen.....	507
Chemistry of tobacco. The essential oil of tobacco, Halle and Příbram.....	508

METEOROLOGY.

Modern methods in meteorology, Fontseré y Riba.....	508
Climatological data for the United States by sections.....	508
Annual report of the Iowa Weather and Crop Service for 1914, Chappell.....	508
The weather of the past agricultural year, Brodie.....	508
The weather of 1914, Gilchrist.....	509
The weather of Scotland in 1914, Watt.....	509
Meteorological observations in Moscow during 1913-14, Leyst.....	509
Meteorological observations.....	509
On the climate of the principal rubber-producing countries, Van Bemmelen...	509
Temperature in cultivated and uncultivated soil, Gilchrist.....	510
The rains of the Nile basin and the Nile flood of 1912, Craig.....	510

SOILS—FERTILIZERS.

Soils of the eastern coal field, Jones.....	510
Soil survey of Webster County, Jones.....	510
Soil survey of the Marrs farm, Jones.....	511
Soil surveys of Hartford, Madisonville, and Central City quadrangle, Jones....	511
Soils of Meade and Breckinridge [Counties], Jones.....	511
Soils and agriculture of the southern New York highland region, Fippin.....	511
Soils from the East Africa Protectorate.....	512
On rubber soils, Mohr.....	512
The acidity of Malayan soils, Barrowcliff.....	512
The inundation of the valley of the Yser, Barois.....	512
Agricultural chemistry and vegetable physiology, Miller.....	512
Soil problems, Leather.....	513
The movement of soluble salts with the soil moisture, Harris.....	513
The rôle of colloids in agricultural soil, den Berger.....	513
Some data on the question of the form of nitrogen in the soil, Shmuk.....	513
Soil bacteriology, Hutchinson.....	513
Protozoa in relation to the factor limiting bacterial activity in soil, Goodey...	515
The biological absorption of phosphoric acid in the soil, Dushechkin.....	515
Comparative effect of phosphates and sulphates on bacteria, Fred and Hart ...	515
A new case of unproductiveness in sugar-cane soils, Ledebœr and Berkhout...	516
A practical way to supply plant food to our soils, Jones.....	516
The composition and value of farm manures, Jensen.....	516
Experiments with barnyard manure at Darmstädt, Wagner.....	516
Bat guanos, Gile and Carrero.....	517
Fertilizer experiments on the red clay soil, Gile and Carrero.....	517
Drill fertilizing, Tacke.....	517
Production of nitrates from air, with a new electric furnace, Scott.....	517
Potassium from the soil, Hopkins and Anmer.....	517
Salines in the Owens, Searles, and Panamint basins, California, Gale.....	518
German potash situation, Lay.....	518
The phosphate deposits of South Carolina, Rogers.....	518
Solubility of the different constituents of slag, Sirot and Joret.....	519
The solubility and assimilability by plants of superphosphate, Kossovich....	519
A new theory regarding the feeding power of plants, Truog.....	519
Chlorosis of sugar cane, Gile and Carrero.....	519
Lime-induced chlorosis, Gile and Carrero.....	520
The purification of waste liquors from paper mills, Kershaw.....	520
Commercial fertilizers, Jones, Jr., et al.....	520
Analyses of commercial fertilizers, Wessels et al.....	520

AGRICULTURAL BOTANY.

	Page.
An experimental study of the rest period in plants: Seeds, Howard.....	520
Experiments in forcing native plants to blossom during the winter, Rosendahl..	521
Effect of shade on transpiration and assimilation of tobacco, Hasselbring.....	521
Absorption of ions by plants, Plate.....	521
Antagonism between ions in absorption of salts by plants, Stiles and Jørgensen..	521
Determination of elements necessary to development of maize, Mazé.....	522
The chlorosis of plants, Mazé.....	522
The influence of fluorin upon vegetation, Gautier.....	522
Resistance of growing plants to hydrocyanic acid fumigation, Cotte.....	522
Action of chloroform and ether on inversion of saccharose in sugar beet, Mazé..	523
Influence of naphthalin on growth in plants, Cacciari.....	523
Formation of starch in the embryo before maturity of the seed, Guilliermond..	523
Starch reserve in birch and maple, Brown.....	523
The origin of anthocyanin in different plant organs, Moreau.....	523
Anthocyanin formation and mineral nutritive components, Czartkowski.....	523
Anthocyanin formation in rose leaves, Löwsehn.....	523
Anatomy of <i>Acacia mollissima</i> , with special reference to tannin, van der Byl..	523
Biochemical investigations of saponins, Korsakoff.....	524
Chemical peculiarity of dimorphic anthers of <i>Lagerstromia indica</i> , Harris.....	524
Studies on the floral biology and pathology of the olive, Petri.....	524
Mutation en masse, Bartlett.....	524
Studies in pea varieties and hybrids therefrom, Kappert.....	525
A flora of Cuba, de la Maza and Roig.....	525
Geography and vegetation of northern Florida, Harper.....	525
Plant ecology and floristics of Salton Sink, Parish.....	525
Movements of vegetation due to submerision and desiccation of land, MacDougal..	525
The behavior of certain micro-organisms in brine, Peirce.....	525

FIELD CROPS.

Root systems of agricultural plants, Maschhaupt.....	526
The influence of phosphatic fertilizers on root development, Watt.....	526
The geographical distribution of the field crops of India, Engelbrecht.....	526
[Studies with field crops in Montana].....	526
Grasses and forage crops.....	526
Experiments on permanent grass land, 1915.....	526
[Fertilizer experiments].....	527
Pasture grasses: Their cultivation and management, Breakwell.....	527
Ecology of the purple heath grass (<i>Molinia caerulea</i>), Jefferies.....	527
A new species of forest grass (<i>Spodiopogon laceri</i>), Hole.....	527
Variety tests with millet and sunflowers, Fedorov.....	527
The effect of the association of legumes and nonlegumes, Ellett et al.....	527
Vegetative regeneration of alfalfa, Wilson.....	528
Experiments with corn in 1914, Svishchev and Aksenov.....	528
Soil moisture and tillage for corn, Mesier and Gustafson.....	528
Tests of varieties of corn, Hanger.....	528
Variety tests of corn for 1914, Garren.....	529
Report on variety tests of cotton for 1914, Winters.....	529
Cauto tree cotton, Cousins.....	529
Factors controlling the ginning per cent of Indian cottons, Leake.....	529
Fiber industry of British East Africa, Wigglesworth.....	530
The growth and preparation of Italian hemp, Wigglesworth.....	530
Investigations on hops.—V, On the aroma of hops, Schmidt.....	530
Investigations on hops.—VI, Lupulin in plants raised by crossing, Schmidt..	530
Investigations on hops.—VIII, Flowering of plants raised by crossing, Schmidt..	530
Results of introducing in 1913 fertilizers on lupines, Kulzhinskii.....	531
Seed potatoes from light soils on richer and heavier soils, Schneidewind.....	531
Pictorial practical potato growing, Wright and Castle.....	531
The prototype of the cultivated sorghums, Piper.....	531
Variations in soy bean inoculation, Voorhees.....	531
The cultivation of sugar beet in Norfolk and Suffolk, Orwin and Orr.....	532
Single-germ beet seed, Townsend.....	532
Report of the seedling expert, Cowgill.....	532
Manurial experiments, Tempany et al.....	532
Catalytic or fecundating stimuli and mutation in <i>Nicotiana</i> , Splendore.....	533

	Page.
The Georgia velvet bean, Belling.....	533
Variation in pure lines of winter wheat, Williams.....	533
Determination of seeds of <i>Cuscuta trifoliū</i> and <i>C. suaveolens</i> , Bernátsky.....	533
The weed <i>Galinsoga parviflora</i> , Müller.....	534
Methods of determining weight per bushel, Love.....	534
A method for testing the breaking strength of straw, Helmick.....	534

HORTICULTURE.

[Report of horticultural investigations].....	534
Report of the horticulturist, Kinman.....	535
Report of the assistant horticulturist, McClelland.....	536
[Floral and vegetable trials at Wisley in 1914], Titchmarsh.....	536
[Miscellaneous floral and vegetable trials at Wisley, 1914].....	536
Cabbage growing in California, Rogers.....	537
The inheritance of size in tomatoes, Perry.....	537
Arboriculture, Savastano.....	537
A guide to the literature of pomology, Bunyard.....	537
Small fruits for home and commercial planting, Sutton.....	537
Addition of soft soap to lead arsenate for spraying purposes, Edwardes-Ker....	538
Spray calendar, Faurot.....	538
New method of obtaining grafted peaches, Manaresi.....	538
Testing grape varieties in the Vinifera regions of the United States, Husmann.....	538
Physiological research on pollen germination in <i>Vitis vinifera</i> , Garino-Canina..	539
Viticulture in Japan, Oinoue.....	539
Some recent experiments on conservation of grapes in various gases, Dalmasso.....	539
Statistics on the production of grapes and olives in 1914.....	539
The methods of reproduction in olive culture, Campbell.....	540
Bench rooting of citrus nursery stock, Ralston.....	540
The lime and the lemon as sources of citric acid and essential oils, Dunlop.....	540
The blood orange in the territory of Caltagirone, Cocuzza.....	540
The cultivation of the hazelnut in the Province of Messina, Stancanelli.....	540
Dahlias tried at Duffryn, 1914.....	540
The gardenette or city back yard gardening by the sandwich system, Albaugh..	540
The use of charcoal as a medium for plant growth, Appleyard.....	540

FORESTRY.

The evolution of forest policy, Descombes.....	541
The use book, a manual for users of the National Forests, 1915.....	541
International Forestry Congress.....	541
Report of department of forestry of Pennsylvania for 1912-13, Conklin.....	541
Forest administration in Assam for 1913-14, Perrée and Monro.....	541
Forest administration in the Jammu and Kashmir State for 1913-14, Lovegrove.....	541
The flowers of the woods, Gatin.....	541
The results of forest culture experiments, Schwappach.....	541
Some Irish larch plantations, Waddingham.....	542
Pine tree culture in Nordland, Lindberg.....	542
Hevea tapping results, Experiment Station, Peradeniya, 1911-1913, Petch.....	542
Hevea tapping results, Experiment Station, Peradeniya, 1914, Petch.....	542
Scientific tapping experiments with <i>Hevea brasiliensis</i> , de Jong.....	542
Tapping and the storage of plant food in <i>Hevea brasiliensis</i> , Campbell.....	543
The tapping of an old Hevea tree at Henaratgoda, Petch.....	543
Notes on the history of the plantation rubber industry of the East, Petch.....	543
The naval stores industry, Schorger and Betts.....	543
Records on life of treated timber in the United States, Weiss and Teesdale....	544

DISEASES OF PLANTS.

Notes on plant diseases in Virginia in 1913 and 1914, Reed and Crabill.....	544
Report of the botanist and mycologist, Petch.....	545
Notes upon Washington fungi, Hall.....	545
The temperature relations of some fungi causing storage rots, Ames.....	545
Further studies on the specialization of <i>Uromyces caryophyllinus</i> , Fischer.....	545
The specialization of <i>Puccinia pulsatillæ</i> , Fischer.....	545
Overwintering of cereal rusts in uredospore form, Montemartini.....	546

	Page.
Rust attack of winter cereals, Hiltner.....	546
Treatment of winter grain with corrosive sublimate, Hiltner.....	546
Chinosol and formaldehyde as protection against Fusarium in cereals, Hiltner ..	546
Limitation and management of grain for seeding, Hiltner.....	546
Use of rusted grain for seed, Hiltner.....	546
Dry spot of oats, Hiltner.....	546
Hiltner's experiments on the control of dry spot of oats, Schoevers.....	557
Some observations on ordinary beet scab, Lutman and Johnson.....	547
Beet scab, Grimm.....	547
Rearing beet nematodes on agar, Berliner and Busch.....	547
Root scab and other celery diseases, Quanjer and Slagter.....	547
Some new bacterial diseases of legumes, Manns.....	547
The life history of Ascochyta on some leguminous plants, II, Stone.....	548
The Rhizoctonia lesions on potato stems, Drayton.....	548
<i>Puccinia endivivæ</i> and rust of prickly lettuce, Maffei.....	548
<i>Protascus colorans</i> , the source of yellow grains in rice, van der Wolk.....	548
Rust of fruit trees, Desmoulins.....	549
Influence of atmospheric conditions on the appearance of downy mildew, Capus.....	549
Oidium of oak and grape, Ravaz.....	549
Report of the plant pathologist, Fawcett.....	549
<i>Pythiacystis citrophthora</i> and its probable relation to mal di gomma, Fawcett.....	550
The citrus root nematode (<i>Tylenchulus semipenetrans</i>) in Florida, Nelson.....	550
Storm and drought injury to foliage of ornamental trees, Hartley and Merrill.....	550
New hosts for some forest tree fungi, Weir.....	550
Notes on the chestnut bark disease, Rogers and Gravatt.....	551
Chestnut blight in Nebraska, Pierce.....	551
Notes on chestnut fruits infected with the chestnut blight fungus, Rumbold.....	551
Notes on Rhizoctonia, Hartley and Bruner.....	551
Observations on <i>Hirneola auricula-judæ</i> , Le Goc.....	551
Further observations on <i>Hirneola auricula-judæ</i> , Le Goc.....	552
Some observations on abortive sporophores of wood-destroying fungi, Weir.....	552

ECONOMIC ZOOLOGY—ENTOMOLOGY.

Zoological philosophy: Natural history of animals, Lamarck, trans. by Elliott..	552
Some Canadian rodents injurious to agriculture, Criddle.....	552
How plague may be carried from place to place.....	552
Rat proofing the public docks of New Orleans, Letton.....	552
The economy of ground squirrel destruction, Long.....	552
<i>Cimex pipistrelli</i> ; nonpathogenicity of <i>Trypanosoma vespertilionis</i> , Pringhault..	552
The bird book, Reed.....	553
Ferty common birds of West Virginia, Brooks.....	553
Some Pennsylvania birds and their economic value, Surface.....	553
The practical value of birds, Henderson.....	553
Some observations on the food of nestling sparrows, Collinge.....	553
Comparative physiology and morphology of the arachnids, I, Dahl.....	553
Bibliography of Canadian entomology for the year 1913, Bethune.....	553
Guide to California insects, Woodworth.....	553
First biennial report of the Montana State Board of Entomology, Cooley.....	553
Report of the entomologist, Van Zwaluwenburg.....	554
Report of State entomologist and plant pathologist for 1914, Bentley.....	554
Injurious insects and other animals in Ireland during 1913, Carpenter.....	554
[Reports of the entomologist of Southern Rhodesia], Jack.....	554
[Insect pests in Mauritius], d'Emmerez de Charmoy.....	554
Insect notes.....	555
Insect pests of field crops, Haseman.....	555
Insect enemies of lucern, Picard.....	555
Injury by tipulids and tabanids in rice fields, Del Guercio.....	555
Protecting cabbage and cauliflower from attacks by worms, Tucker.....	555
The cochylis, eudemis, and pyralid moths and altisa beetle, Clarió-Soulán.....	555
[Insect pests of coconuts and cacao].....	555
Two years' study of insects in relation to pellagra, Jennings.....	555
Spraying for apple sucker and leaf-curling plum aphid, Petherbridge.....	555
Effect of cyanid of potassium on trees, Shattuck.....	556
New fumigating machines, Gray.....	556

	Page.
Cyanid fumigation of ships, Roberts.....	556
On certain peculiar fungus parasites of living insects, Thaxter.....	556
An outline of the subfamilies and higher groups of the Thysanoptera, Hood....	556
The grape leafhopper, Merrill.....	556
<i>Psylla piri</i> and the fight against it, Gudkov.....	556
Spraying for the control of the walnut aphid, Taylor.....	557
The host plants of <i>Aphis rumicis</i> , Davidson.....	557
Spraying eggs for control of purple and green apple aphids, Jones.....	557
Life history and habits of the rose scale, <i>Aulacaspis rosæ</i> , Nakayama.....	557
The San José and oyster-shell scales, Cæsar.....	558
The citricola scale, Quayle.....	558
The efficiency of fungoid parasites of scale insects.....	558
Poison glands of the larva of the brown-tail moth, Kephart.....	558
Life history of the codling moth in Maine, Siegler and Simanton.....	559
The sugar cane bud moth (<i>Loxostoma</i> sp.), Jarvis.....	560
The grass moth (<i>Remigia repanda</i>), Bodkin.....	560
Flies in relation to disease.—Bloodsucking flies, Hindle.....	560
Dr. A. F. A. King on mosquitoes and malaria, Howard.....	560
Biology of North American crane flies.—III, The genus <i>Ula</i> , Alexander.....	561
Notes on the life history and anatomy of <i>Siphona plusiæ</i> , Bloeser.....	561
The house fly (<i>Musca domestica</i>), Hewitt.....	561
The feeding habits of the stable fly, <i>Stomoxys calcitrans</i> , Hewitt.....	561
Cherry fruit flies, Cæsar and Spencer.....	561
Ravages, life history, and control of the melon fly, Severin and Hartung.....	562
The progress of <i>Scymnus bipunctatus</i> , Smith.....	562
Some notes on life history of lady beetles, Palmer.....	562
The violet rove beetle, Chittenden.....	563
The small sweet potato weevil (<i>Cryptorhynchus batatæ</i>), Whitney.....	563
Recent studies of the Mexican cotton boll weevil, Coad.....	563
Bee keeping for profit, Morley.....	563
The orientation of ants and the orientation problem in general, Brun.....	563
Chalcidids of the Isosoma injurious to grain in Russia, Rimsky-Korsakov.....	563
[Studies of the Siphonaptera or fleas], Fox.....	563
A synopsis of the British Siphonaptera, Rothschild.....	563

FOODS—HUMAN NUTRITION.

Composition of grain, flour, and offals of four varieties of wheat, Hunter.....	564
Durum wheat as a substitute for other grain in bread making, Caselli.....	564
Composition of corn-meal products and digestibility of protein, Rammstedt....	564
The chemistry of rice polishings, Fraser and Stanton.....	564
Nature of the sugars found in the tubers of sweet potatoes, Miyake.....	564
On the nuclein bases found in the shoots of <i>Arabia cordata</i> , Miyake.....	564
Are the hardened fats suitable food for man? Süßmann.....	564
Does butter fat contain nitrogen and phosphorus? Osborne and Wakeman....	564
Chemical composition of Hungarian flower honeys, Weiser.....	565
Molasses, McGill.....	565
Economical electric cooking.—Competition with gas and coal, Gumaer.....	565
Report of New York State Food Investigating Committee, Brown et al.....	565
Relation of pellagra to use of foods and location of domicile, Siler et al.....	565
Studies on the digestion of cooked meat in the case of dogs, Zunz.....	565
The utilization of vegetable protein by the animal organism, Boruttau.....	565
The specific heat of muscle protein and its significance, Krummacker.....	566
Absorption of protein and fat in depancreatized animals, Cruickshank.....	566
The metabolism of creatin and creatinin, VII, Myers and Fine.....	566
The metabolism of creatin and creatinin, VIII, Myers and Fine.....	566
The metabolism of creatin and creatinin, IX, Myers and Fine.....	566
Does cholesterin exert an influence on cholesterin in bile? d'Amato.....	566
Bodily changes in pain, hunger, fear, and rage, Cannon.....	566
A study of prolonged fasting, Benedict.....	566
Basal metabolism and body surface—a contribution to normal data, Means....	567
The water content and temperature of expired air, Galeotti.....	567
The temperature of expired air, Galeotti, Scaffidi, and Barkan.....	567
Micro-calorimetry applied to animal tissues, DeAlmeida.....	567
Investigations at nutrition laboratory of Carnegie Institution, Benedict.....	567

ANIMAL PRODUCTION.

	Page.
Foodstuffs for animals and their valuation, Stockdale.....	568
Some facts about concentrated feeds, Strowd.....	568
Vine prunings as fodder, de Castella.....	568
Silage feeding, Bray.....	568
The comparative values of cotton seed, cotton seed meal, and corn, Francis...	568
Coconut cake and palm-nut kernel cake.....	568
The feeding value of refuse brewers' yeast: Hungarian experiments, Schandl..	568
Action of taka-diastase on digestive power of healthy animal, Sawamura.....	569
A new method for determination of live weight of cattle, Mascheroni.....	569
The cost of maintenance of cattle, Trowbridge, Moulton, and Haigh.....	569
Growth of pasture animals, Falke.....	570
Calf feeding experiment, 1914, Foulkes, Andrews, and Garnett.....	570
Sheep breeding experiments, Foulkes, Andrews, and Garnett.....	570
Effect of dips on wool, Enslin.....	571
[Pig] feeding experiments, Roulston et al.....	571
Swine-feeding experiments with a sugar feed, Richardsen.....	571
The value of fish and meat meals for fattening pigs, Martinoli.....	571
Artificial impregnation of mares, von Nemeshegny.....	571
Care and training of trotters and pacers, Thomas and Shields.....	571
The historical development of poultry husbandry in Germany, Beeck.....	572
A poultry survey of the city of Ithaca, Kent.....	572
Animal food for poultry, Jackson.....	572
The value of mineral elements in poultry feeding, Jull.....	572
A résumé of chick feeding, Nixon.....	572
Report of second twelve months' poultry laying competition, 1913-14, Brown..	572
Inbreeding.—Its effect on vigor and egg laying, Dryden.....	572
Additional data on effect of castration in domestic fowl, Goodale.....	573
On the rhythm of egg production, Goodale.....	574
Carbon dioxid thrown off by eggs during incubating, Atwood and Weakley, Jr...	575
Peacock-guinea fowl hybrids, Brentana.....	575
Bibliography [of poultry literature].....	575

DAIRY FARMING—DAIRYING.

The value of barley for cows fed alfalfa, True, Woll, and Voorhies.....	575
Prolificacy in the breeds of dairy cattle.....	576
Holstein makes new world's record.....	576
The dairyman v. the dairy, North.....	576
The score-card system for the inspection of dairy farms.....	576
A survey of the milk situation in Kansas, Congdon.....	577
The importance of milk sugars for the hygienic judging of milk, Gabathuler..	577
Sore throat and the virulence of streptococci from milk, Rosenow and Moon...	577
The advantages and disadvantages of preservatives in food, Robertson.....	577
Tables for blending milk and cream, McNally.....	577
How to make creamery butter on the farm, McLaughlin.....	577
The manufacture of cheese with selected ferments, Samarani.....	577
Blue-veined cheese, or Dorset "Vinny".....	578
Chemical examination of ghee, Vakil.....	578
Bibliography of dairy literature, compiled by Brosch.....	578

VETERINARY MEDICINE.

Epizootic abortion, Stockman.....	578
Differential diagnosis of anthrax and pseudoanthrax bacilli, Pokschischewsky..	579
An unusual result following anthrax vaccination and a lesson, Ravenel.....	580
Eradication and treatment of foot-and-mouth disease, IV, Hoffman.....	580
Further observations on the effect of quinin in rabies, Moon.....	580
Experimental study of distribution and habitat of tetanus bacillus, Noble....	580
Some further investigations on hog cholera, Uhlenhuth et al.....	580
When to vaccinate against hog cholera.....	582
Diseases of respiratory tract of horse which resemble glanders, Joest.....	582
Microfilariasis of the horse in Turkestan, Yakimow et al.....	583

RURAL ENGINEERING.

	Page.
Tenth biennial report of the State engineer to the governor of Idaho.....	583
Irrigation investigations in Wyoming, 1913-14, Johnston.....	583
Water conservation and irrigation.....	583
Duty of water investigations, Bark.....	583
Irrigation works in Italy, Luigi.....	584
Working data for irrigation engineers, Moritz.....	585
Land drainage, Parsons.....	585
Florida Everglades.....	585
Water conveyance and drainage works.....	586
Preliminary estimating of canal excavation, Hammond.....	586
Rock-fill dam with some extraordinary foundation problems, Hinderlider.....	586
Concrete chute drops water 130 feet from canal to reservoir, Cole.....	586
New type of gate for regulating adjacent water levels operates automatically..	586
Water supplies, Rideal.....	586
Water supplies in the Philippine Islands, Cox, Heise, and Gana.....	587
The influence of the forest on the water supply, Henle.....	587
The importance of forests with reference to the water supply, Ney.....	587
Hypochlorite treatment of water supplies, Whittaker.....	588
Water and sewage, Müller et al.....	588
Report of the state highway commission of Minnesota for 1914.....	588
Concrete roads v. macadam, McAlister.....	588
Design of concrete highway bridges with special reference to standardization..	588
The economic design of culverts for various depths of fills, Sheidler.....	588
Effect of temperature on the strength of cement mortar.....	589
Use of electricity for irrigation and on the farm, Williams.....	589
When the gas engine will not start, Percy.....	589
Progress in small farm tractors, Ellis.....	589
International competition of motor tillage machines at Chaouat, Tunis, 1914..	589
Tests of two milking machines, Martiny and Vieth.....	589
A shearing shed, sheep yards, and dip, McFadzcan.....	589
A shearing shed for small flocks, Mathews.....	589
Fences and fencing.....	589
Country plumbing practice, Hutton.....	590
Farm sanitation, Wright.....	591
Methods of sewage disposal for country homes, Ball and Cassidy.....	591
Sewage disposal in the country.....	591
Investigations on the disposal of canning factory wastes, Englis.....	591

RURAL ECONOMICS.

Agricultural cooperation and rural credit in Europe.....	592
Agricultural cooperation and rural credit in Europe, III.....	593
Report of the Irish Agricultural Organization Society, Limited, 1914.....	593
Social and economic survey of a community in the Red River Valley, Weld..	593
The study of a rural parish, Felton.....	593
Mortality statistics, 1913.....	594
National subsistence and agricultural colonization, Kranold.....	594
[Agriculture in Norway].....	594
Agriculture in Serbia, Waldmann.....	594
Estimates of area and yield of principal crops in India, 1913-14.....	594
Pineapple-canning industry of the world, Shriver.....	594
Monthly crop report.....	594
Farmers' market bulletin.....	594

AGRICULTURAL EDUCATION.

First annual report on vocational education in Indiana, Book.....	595
State-aided vocational agricultural education in 1914.....	595
Agriculture in the New York State high schools, Hawkins.....	595
[Agricultural education in the Philippines].....	595
A new year in agricultural instruction.....	596
Elementary agricultural instruction.....	596
Vocational education in Europe, Cooley.....	596
Regulations for grants in England and Wales, 1915-16.....	596

	Page.
Agricultural training for women in Holland, von Ramult.....	596
Education for efficiency, Davenport.....	596
The proper preparation of teachers in schools of agriculture, Maphis.....	596
School credit for home work, Alderman.....	597
Teaching agriculture in rural and graded schools, Bishop et al.....	597
Lessons in elementary agriculture for Alabama schools, Miller.....	597
Pre-vocational agricultural courses for the public schools of Indiana.....	597
Elementary principles of agriculture, Ferguson and Lewis.....	597
Practical lessons in agriculture, Ivins and Merrill.....	597
A study of Indian corn (<i>Zea mays</i>), Rundles.....	597

EXPERIMENT STATION RECORD.

VOL. XXXIII.

ABSTRACT NUMBER.

No. 6.

RECENT WORK IN AGRICULTURAL SCIENCE.

AGRICULTURAL CHEMISTRY—AGROTECHNY.

A rapid method of estimating nitrates, E. KNECHT (*Jour. Soc. Chem. Indus.*, 34 (1915), No. 3, pp. 126, 127).—Titanous hydroxid causes an instantaneous reduction of nitrates to ammonia. "When caustic soda is added to a solution of a titanous salt, black titanous hydroxid is precipitated, but this begins to decompose almost at once, yielding nascent hydrogen and the white titanic hydroxid, probably according to the following equations:

"A convenient amount of nitrate for a single estimation is about the equivalent of 0.1 gm. potassium nitrate. Thus, in the assay of a commercial sodium nitrate, about 1 gm. is accurately weighed, dissolved in water, and made up to 100 cc. Of this, 10 cc. are measured into a copper flask, excess of caustic soda is added, and then about 20 cc. of commercial titanous sulphate or chlorid. The distillation can then at once be proceeded with and, after the boiling has been continued for a quarter of an hour, the operation is finished and back titration is effected."

Nitrites are also quantitatively reduced to ammonia by titanous hydroxid when an excess of caustic alkali is present.

The estimation of protein ammonia, L. W. WINKLER (*Ztschr. Angew. Chem.*, 27 (1914), No. 56, Aufsatzteil, p. 440, fig. 1; *abs. in Jour. Soc. Chem. Indus.*, 33 (1914), No. 15, p. 804).—Instead of determining the organic matter in water by making a cumbersome albuminoid ammonia determination, the author suggests determining the protein ammonia.

The method proposed consists essentially of treating 100 cc. of the water, acidified with one drop of concentrated sulphuric acid, with 0.05 gm. of pure powdered potassium persulphate, heating in the steam bath for 15 minutes, cooling, and determining the ammonia in the fluid by the Nessler colorimetric method, adding 5 cc. of a mixture of equal volumes of Nessler's reagent and a solution of Rochelle salts. A second test is prepared in the same manner, without heating, adding standard ammonium chlorid solution to equal the color of the first test. Distillation is not necessary in the process.

There are two disadvantages in the method, one being that even the purest potassium persulphate contains ammonia, and the other, the unstability of the potassium persulphate solution. The first can be obviated by recrystallization

from warm potassium hydroxid solution and the latter by acidifying with concentrated sulphuric acid.

It was found that pure natural waters contain no protein ammonia, the limit for a drinking water being set at 0.1 mg. per liter.

Oxidation of carbohydrates and related substances by means of potassium persulphate, J. K. WOOD and NELLIE WALKER (*Jour. Chem. Soc. [London]*, 105 (1914), No. 618, pp. 1131-1140, fig. 1; *abs. in Jour. Soc. Chem. Indus.*, 33 (1914), No. 10, p. 561).—Aldoses may be almost quantitatively oxidized with potassium persulphate in the cold and the process may be accelerated by the addition of small quantities of silver sulphate. Galactose, arabinose, and xylose are oxidized at about the same rate, polyhydric alcohols and dextrose more slowly, while ketoses and disaccharids are attacked somewhat more rapidly than the aldoses.

Analytical work, P. L. GILE and J. O. CARRERO (*Porto Rico Sta. Rpt.* 1914, p. 13).—A comparison of the potassium sulphocyanate colorimetric method for iron with the permanganate method indicated that the former was preferable for the determination of the small amounts of iron contained in most plant substances.

Determination of eggs in food pastes, L. FARCY (*Ann. Falsif.*, 7 (1914), No. 66, pp. 183-187).—The soluble nitrogenous substances in food pastes were estimated before and after boiling, as suggested by Rousseaux and Sirot (*E. S. R.*, 31, p. 809). The purpose was to determine whether or not eggs had been used in the goods under examination.

The ferments of honey, F. GOTHE (*Ztschr. Untersuch. Nahr. u. Genussmitl.*, 28 (1914), No. 6, pp. 273-286, fig. 1; *abs. in Ztschr. Angew. Chem.*, 27 (1914), No. 99, *Referatenteil*, p. 700).—Lactase, proteases (peptic and tryptic), and lipase could not be detected in honey. Inulase is probably present. Invertase in honey is of both animal and vegetable origin, and in genuine bee honey its amount is greater than in feeding honey. It is destroyed at 60° C. and has its optimum of activity at 40°. Catalase and diastase are not present in the same proportion in honey. By filtering honey a marked reduction of catalytic power occurs, and when much impurity is present in honey it is evidenced by a high catalase figure. Honey catalase is markedly affected by heating for one hour at 60° C. (undiluted honey at 70°).

Experimental studies on honey diastase activity as well as the judgment of honey by its diastase content, F. GOTHE (*Ztschr. Untersuch. Nahr. u. Genussmitl.*, 28 (1914), No. 6, pp. 286-321, fig. 1; *abs. in Ztschr. Angew. Chem.*, 27 (1914), No. 99, *Referatenteil*, pp. 700, 701).—Honey diastase is of both animal and vegetable origin. Its quantitative estimation enables an estimate of the value of a honey. A high diastase figure indicates absolutely pure honey. If a medium figure is obtained, Fiehe's test, the precipitation test, and other tests should be made to exclude the suspicion of adulteration. A low diastase figure indicates a low-grade product which has been either overheated or adulterated. Heating undiluted honey for one hour at from 85 to 90° C. destroys the diastase. Diluted honey loses its activity at 70°.

Estimation of chlorin ions in honey, F. E. NOTTBOHM (*Ztschr. Untersuch. Nahr. u. Genussmitl.*, 28 (1914), No. 5, pp. 255-259; *abs. in Ztschr. Angew. Chem.*, 27 (1914), No. 99, *Referatenteil*, p. 700).—By directly ashing honey more than one-half of the chlorin is lost. This may be prevented, especially in honey high in chlorin, by adding bicarbonate of soda.

About the preservation of milk samples for examination purposes, J. TILLMANS, A. SPLITTGERBER, and H. RIFFAERT (*Ztschr. Untersuch. Nahr. u. Genussmitl.*, 27 (1914), No. 12, pp. 893-901).—Mercuric chlorid in a concentration of from 0.04 to 0.03 per cent conserved milk samples for 120 hours. Samples so pre-

served are said to show no appreciable increase in acidity, and the mercuric chlorid had no noticeable effect on the milk constituents. Other substances tested in this regard were chloroform, thymol, oil of mustard, phenol, creosote, sodium fluorid, and potassium bichromate.

Investigations upon the changes which take place in milk preserved with potassium bichromate, A. KLING, GELIN, and LASSIEUR (*Ann. Falsif.*, 7 (1914), No. 67, pp. 244-250).—Potassium bichromate is a convenient, although not an ideal, preservative of milk. If 1 gm. is added to 1 liter of fresh milk the sample is fit for examination for a period of 2 months, and milk preserved with 3 gm. per liter will keep fresh for 3 months. In this study phenol as advocated by Denigès (E. S. R., 30, p. 14) was also used for comparison. Milk preserved with bichromate of potash and kept at 27° C. coagulated much quicker than milk which was stored at from 18 to 20°.

The action of milk mold on phenylaminoacetic acid, H. HORSTERS (*Biochem. Ztschr.*, 59 (1914), No. 5-6, pp. 444-450).—*Oidium lactis* when grown on a solution containing phenylaminoacetic acid, monopotassium phosphate, magnesium sulphate, traces of sodium chlorid, ferric chlorid, and either dextrose or invert sugar elaborated benzyl alcohol, very small traces of phenylglyoxylic acid, benzoic acid, traces of formic acid, and 1-mandelic acid.

Volumetric estimation of casein in milk by the aid of tetraserum, B. PFYL and R. TURNAU (*Arb. K. Gsndhtsamtl.*, 47 (1914), No. 3, pp. 347-361).—As a preliminary casein was prepared from cows' milk and its nitrogen and acid equivalents were determined. The average nitrogen content was 15.5 per cent, which corresponds to a factor of 6.45 per cent. For neutralizing 1 gm. of casein toward phenolphthalein 8.75 cc. of decinormal alkali was necessary on the average, indicating an acid equivalent of 1,143. The method for determining casein was as follows:

To 50 cc. of the milk under examination, cooled to 15° C., add from 5 to 6 drops of a 1 per cent phenolphthalein solution and titrate to a pink color with decinormal (carbonate free) alkali solution. Treat another 50 cc. of milk in a stoppered bottle with about 5 cc. of carbon tetrachlorid, shake thoroughly, treat with exactly 1 cc. of a 20 per cent acetic acid solution (of known titer), then shake again, and filter. Then titrate 25 cc. of the serum, after adding from 2 to 3 drops of a 1 per cent phenolphthalein solution, with decinormal alkali solution until a pink tint appears. From the first titration and the titer of the 20 per cent acetic acid solution the alkali required for 25 cc. of milk+0.5 cc. of acetic acid (a =amount of alkali solution) is determined. From this result, the alkali required for titrating the serum (b =cc. of decinormal alkali solution), and the fat content of the milk (f =gm. of fat in 100 cc. of milk) the casein content is calculated:

$$g = \text{the casein in 100 cc. of milk} = 0.457 \left(a - b \frac{99.3 - f}{100} \right)$$

The derivation of the formula is discussed and some results obtained with the method are included. With heated milk the procedure gave correct results. This was not the case with either the Schlossmann or Hoppe-Seyler methods. See also previous notes by Hart (E. S. R., 19, p. 707; 21, p. 613).

Old and new methods for determining fat in milk, A. V. OVEN (*Milchw. Zentbl.*, 43 (1914), Nos. 11, pp. 285-295; 13, pp. 350-356).—A review of the literature, especially with reference to the methods in use in Europe.

Determination of lactose in milk by the polarimetric method, E. FEDER (*Ztschr. Untersuch. Nahr. u. Genussmitl.*, 28 (1914), No. 1, pp. 20-29; *abs. in Ztschr. Angew. Chem.*, 27 (1914), No. 72-73, *Referatenteil*, p. 533).—To 75 cc. of milk add 6 cc. of asaprol solution (consisting of 75 gm. of asaprol and 75 gm.

of citric acid to 250 cc. of solution), fill up to the 100 cc. mark, and after standing for 15 minutes filter and polarize. One degree of rotation to the right in circular instruments and sodium light at 20° C. in a 200 mm. tube=0.9518 gm. of milk sugar. If the rotation $\times 0.9518 = a$, the lactose content $M =$

$$100.8 - t + \frac{96.7 - f}{a} \frac{a}{75}$$

t =percentage of total solids and f =percentage of fat in milk.

The estimation of the viscosity of milk as an aid for detecting added water, W. D. KOOPER (*Milchw. Zeitbl.*, 43 (1914), Nos. 7, pp. 169-179, fig. 1; 8, pp. 201-208).—In these studies composite milks were principally examined. The apparatus used is illustrated and described.

The expression of the viscosity is analogous to that used by Engler in reporting the viscosity of oils. The degree of viscosity in the milk seems to be an expression of the total solids content and its determination will enable one to detect added water or the removal of cream. With the method at least 5 per cent of water may be found. The fat content of the milk apparently does not influence the viscosity to the extent suggested by Micault,^a and although an increased fat content is expressive of an increased viscosity there are instances where the reverse is the case. A still smaller relation exists between the specific gravity and the viscosity. A milk diluted with 25 per cent of added water has a higher viscosity than unadulterated milk. If, however, the viscosity obtained is divided by the factor 0.1384 the total solids content of the milk may be approximately estimated.

Detection of goat's milk in cow's milk, J. PRITZKER (*Chem. Ztg.*, 38 (1914), No. 93, pp. 982, 983; *abs. in Jour. Soc. Chem. Indus.*, 34 (1915), No. 4, p. 195).—The test depends upon the difference in behavior of the two milks with ammonia.

The freezing point of some abnormal milks, J. B. HENDERSON and L. A. MESTON (*Proc. Roy. Soc. Queensland*, 26 (1914), pp. 85-90; *abs. in Jour. Soc. Chem. Indus.*, 34 (1915), No. 4, p. 195).—Two samples of mixed milks from eight animals, badly fed and in poor condition, were found to be low in solids not fat (7.74 and 7.79 per cent) but had a normal freezing point (−0.55 and −0.54° C.). When the milk from each animal was examined only one of them was found to give a normal milk, but in every case the freezing points were within the normal limits (−0.54 and −0.56°). The ash of the milk contained large amounts of chlorin (up to 31 per cent). This is regarded as evidence of the power of the mammary glands to regulate the osmotic pressure through the extraction of an increased amount of sodium chlorid from the blood in order to compensate for the deficiency of other constituents.

The electrical conductivity of milk during its concentration, with suggestions for a practical method of determining the end point in the manufacture of sweetened condensed milk, LILIAS C. JACKSON, L. McNAB, and A. C. H. ROTHERA (*Jour. Soc. Chem. Indus.*, 33 (1914), No. 2, pp. 56, 60).—The maximum electrical conductivity is noted when morning milk is concentrated to 28 per cent total solids with 8 per cent protein. Evening milk gives higher figures. The electrical conductivity is deemed of no value in determining the degree of concentration of a separated unsweetened milk because the concentration may increase considerably between 25 and 30 per cent of total solids with very little alteration in the conductivity. "It is quite different, however, with a sweetened milk concentrated to the degree which is usual in the manufacture of condensed milk. With full fat, and with added cane sugar equivalent approximately to 16 lbs. sugar per 100 lbs. milk, the reversal of the conductivity comes at the

start of the process of concentration. When the concentration reaches the necessary degree for the production of sweetened condensed milk, the electrical conductivity decreases rapidly for each increase in concentration of the milk. . . . From theoretical considerations supported by experimental work in the laboratory, there is every reason to think that the measurement of electrical resistance or conductivity should furnish an accurate method of following the progress of concentration in the manufacture of sweetened condensed milk."

Dry milk with particular reference to determining the fat content, Urtz (*Milchw. Zentbl.*, 43 (1914), No. 5, pp. 113-120).—The determination of water, ash, nitrogen, and lactose in dry milk is comparatively simple but certain difficulties are experienced when fat is to be estimated by the usual methods. A modification of the Bondzynski-Ratzlaff method and the Polenske method (E. S. R., 25, p. 12), is recommended for determining the fat in this kind of material. Gerber's method did not yield satisfactory results.

The acidity degrees (Soxhlet-Henkel) were determined in 26 samples of powder made from whole milk, cream, partly skimmed milk, and skim milk. The method employed is as follows: About 80 cc. of a neutral alcohol-ether mixture is poured over 10 gm. of the air-dry milk powder, shaken at intervals, and after 24 hours the mixture is made up to a volume of 100 cc. The number of cubic centimeters of decinormal alkali required to neutralize 50 cc. of the solution is calculated in the same manner as employed for fats and oils.

Some data are being collected regarding the acidity of dry milk stored over a long period of time.

A critical study of Césaro's method for the detection of coconut fat in butter, L. STÖELIN (*Ann. Falsif.*, 7 (1914), No. 67, pp. 223-231).—It is stated that the Césaro method^a can be employed for detecting coconut fat in butter. If the fat added is solid as little as 10 per cent can be detected, but when added in a liquid state only 25 per cent can be noted. Additions of less than 10 per cent can not be noted with certainty.

Rapid analysis of butter: Estimation of nonfats, E. ISNARD (*Ann. Falsif.*, 7 (1914), No. 69, pp. 369-371).—For the purpose of determining especially the nonfatty materials in butter, from 2 to 3 gm. of butter is weighed into a porcelain dish, and 10 cc. of water is incorporated on the water bath. The emulsion is then brought into a separatory funnel and cooled to 35° C. Ten cc. of water and from 20 to 30 cc. of ether are then used to remove the fatty materials adhering to the sides of the dish, the washings are transferred to the funnel, and the mixture is shaken cautiously. After 15 minutes standing the aqueous layer with the supernatant casein is drawn off, two portions of 10 cc. each of water are added, and the process of shaking with water and drawing off is repeated twice. The ether layer is then transferred to a dish, the ether is dispelled by a current of air, and the residue dried at 100° C. In the aqueous portion the casein is determined by collecting it on a filter. The total solids contained in the filtrate represents casein, albumin, and salts. The latter can be determined by incinerating the residue.

Extraction of neutral fats from ripe sheep's milk cheese for the purpose of determining the chemical and physical constants of the same, F. BÁRÁNY (*Ztschr. Untersuch. Nahr. u. Genussmitl.*, 28 (1914), No. 1, p. 33; *abs. in Ztschr. Angew. Chem.*, 27 (1914), No. 72-73, *Referatenteil*, p. 533).—For this purpose 80 gm. of cheese is rubbed up with 15 cc. of water to a paste and brought up to a bulk of 250 cc. by the addition of water. The mixture is neutralized toward phenolphthalein, with potassium hydroxid solution made up to a bulk of 300 cc., shaken vigorously with 300 cc. of petroleum ether, 300 cc. of 95 per cent alcohol

^aAcad. Roy. Belg., *Bul. Cl. Sci.*, 1907, No. 12, p. 1004.

added, and the mixture shaken again. After standing from 24 to 48 hours the clear petroleum ether layer is removed, the solvent dispelled by distillation, and the residue dried at 100° C.

Determination of unsaponifiable matter in oils and fats, H. SALOMON (*Ber. Deut. Pharm. Gesell.*, 24 (1914), No. 3, pp. 189-193).—It is stated that the modification of the Marcusson and Schilling method proposed by Klostermann can be extended so as to allow at the same time the estimation of unsaponifiable matter.

From 50 to 100 gm. of oil or fat is saponified with alcoholic potash solution and the resulting soap dissolved in water, extracted with ether, and after dispelling the ether from the extract drying and weighing the residue. The crude phytosterol is dissolved in hot alcohol and precipitated with an excess of digitonin solution, 1 gm. of crystalline digitonin being required for each 0.4 gm. of unsaponifiable matter. The precipitate resulting is collected, acetylated, and the phytosterol acetate recrystallized according to the Klostermann procedure. The unsaponifiable material in the filtrate can be determined by adding water, extracting with ether, and weighing the ether extract after removing the ether. Some tabulated results are given.

Rice oil and rice fat, J. DAVIDSOHN (*Seifenfabrikant*, 34 (1914), pp. 178, 179; *abs. in Ztschr. Angew. Chem.*, 27 (1914), No. 66-69, *Referatenteil*, p. 518).—The rice oil obtained from rice bran by extracting or pressing is a mixture of solid and fluid substances. The portion of the substances solid at room temperature melts at 24° C. Freshly ground bran yields an oil with only a small amount of fatty acids, but when old contains a large amount of these acids. Rice oil has a specific gravity of 0.8907 at 99°, a saponification number of 193.2, and an iodine number of 96.4 according to Smethan or of 91.65 according to Browne. On storage the oil separates into a compact fat and a supernatant clear oil of dark-greenish color, which can be saponified very easily. Its value for the manufacture of soap is pointed out.

The estimation of hydrocyanic acid in feeding stuffs and its occurrence in millet and guinea corn, J. R. FURLONG (*Analyst*, 39 (1914), No. 463, pp. 430-432; *abs. in Jour. Soc. Chem. Indus.*, 33 (1914), No. 21, p. 1069).—According to this method 100 gm. of the ground material under examination is placed in a Soxhlet apparatus and extracted for three hours with 10 per cent alcohol. The extract, after removing the alcohol by distillation, is distilled with 150 cc. of 10 per cent sulphuric acid, the distillate being collected in 5 cc. of 10 per cent potassium hydroxid solution. At the end of one hour the receiver is changed, water added to the distillation flask, and the distillation continued. This operation is repeated until no more hydrocyanic acid is evolved.

“The distillate is concentrated to 15 cc., boiled for 10 minutes after the addition of 1 cc. of a 20 per cent solution of ferrous sulphate containing also 1 per cent of ferric chlorid, cooled, acidified with hydrochloric acid, and 10 cc. of glycerol added. After standing for about 18 hours the mixture is transferred to a graduated cylinder, diluted to 50 cc. with water, and the blue coloration compared in tubes of 1 in. diameter with standards prepared from known quantities of hydrocyanic acid. When the amount of hydrocyanic acid present is not less than 0.001 gm. the standards may be made up directly, but with smaller quantities it is necessary to dilute to 150 cc. and then concentrate as in the preparation of the solution from the plant material.

“From determinations of hydrocyanic acid in millet and guinea corn plants of various ages it was found that all the young plants contained a cyanogenetic glucosid, while the full-grown plants were free from this substance. In the case of guinea corn the yield of hydrocyanic acid reached a maximum (0.01 per cent) in the 12-in. plants and decreased as growth proceeded. With millet

the maximum amount of hydrocyanic acid (0.045 per cent) was found in the 24-in. plants."

Solvents employed in the determination of hop-bitter constituents and their estimation by means of cold extraction, R. SEIBRIGER (*Wehnschr. Brau.*, 30 (1913), Nos. 12, pp. 177-179; 13, pp. 196-198, fig. 1; *abs. in Chem. Abs.*, 7 (1913), No. 19, p. 3387).—The author states that by constantly shaking hops with cold petroleum ether (boiling point 30 to 50° C.), the bitter principle can be removed in from three to four hours. This can also be accomplished by shaking with carbon tetrachlorid in the cold for from one to two hours, but the results are higher. Boiling petroleum ether gives intermediate results.

Investigation on hops.—IV, A method for quantitative determination of resins in hops, Ö. WINGE and J. P. H. JENSEN (*Compt. Rend. Lab. Carlsberg*, 11 (1914), No. 2, pp. 116-147).—It is pointed out that the valuation of hops for brewing purposes must be made on the basis of the chemical analysis, and the object of this work was to find a convenient method whereby hops could be valued by chemical means without the services of a skilled operator. It is believed that an approximately correct expression of the value of hops can be obtained by the following cold extraction method:

Thirty gm. of hops is comminuted by passing through a meat chopping machine. The first 5 gm. coming through the machine is discarded and the remainder coming through, which is usually about 15 gm., is carefully mixed. Five gm. of this, corresponding to a volume of 25 cc., is removed with a measuring glass and placed in a 300-cc. Erlenmeyer flask of known weight. The flask, with its contents, is weighed, dried in a vacuum desiccator for 24 hours at 35° C. over sulphuric acid, and again weighed, the loss in weight representing the moisture content of the hops. Then 150 cc. of water-free ethyl ether is added, the mixture allowed to stand for about one-half hour, with repeated shakings, the ether extract is filtered into an Erlenmeyer flask, and the residue and filter washed with 100 cc. of ethyl ether. The ether extract is then titrated with twentieth-normal potassium hydroxid solution in 93 per cent alcohol, using from 6 to 8 drops of a 1 per cent phenolphthalein in 93 per cent alcohol as the indicator, until a permanent red tint is obtained. Since 1 cc. of the normal potassium hydroxid solution corresponds to 0.4 per cent of resin, the percentage of resin in water-free hops is equal to this factor multiplied by the number of cubic centimeters of potassium hydroxid solution utilized, divided by the total solids of the hops.

A method for the recovery of the ether used is described.

The resin of hops, contrary to previous opinion, is considered of value, because it gives flavor to the wort and aids in the precipitation of the proteins. "Although the resins of hops, which are all soluble in cold ethyl ether, are not all equally bitter and equally valuable—the relation between their bitterness can be expressed by the proportion $\alpha : \beta : \gamma = 10 : 7 : 4$ —yet the total quantity of resins extracted from the hops by means of cold ether and determined by titration is an approximately accurate expression of the bitterness value of hops."

A comparative study was made between the cold ethyl ether extracts made and the carbon tetrachlorid method of Seibriger. See also work by Tartar and Bradley previously noted (*E. S. R.*, 27, p. 814).

Investigations on hops.—VII, The employment of artificial light in titration of the resins in hops, S. H. LARSEN (*Compt. Rend. Lab. Carlsberg*, 11 (1915), No. 4, pp. 184-187, figs. 2).—In the course of work on the quantitative determination of resins in hops by the Winge and Jensen method, noted above, it was found that on dark or cloudy days difficulty was experienced in noting the end point during the titration process. A titration table was devised to

obviate this difficulty. It consists of a wooden box with one side replaced by a removable ground-glass plate. The source of light is a 25-candlepower incandescent lamp. Some results of experiments with and without artificial light are included.

Chemistry of tobacco. The essential oil of tobacco, W. HALLE and E. PŘIBRAM (*Ber. Deut. Chem. Gesell.*, 47 (1914), No. 7, pp. 1394-1398).—An essential nitrogen-free oil acid in reaction was isolated from Hungarian tobacco with solvents. The amount obtained was 0.047 per cent. A hydrocarbon of the formula $C_{10}H_{18}$ or $C_{11}H_{20}$, boiling point 73 to 76° C. at 20 mm., was obtained from the lower boiling fractions. The oil before being submitted to distillation was treated with sodium carbonate. When oxidized with potassium permanganate it yielded compounds resembling terephthalic and isobutylic acids. Isovaleric acid was separated from the sodium carbonate solution used in treating the original solution.

METEOROLOGY.

Modern methods in meteorology, D. E. FONTSERÉ Y RIBA (*Mem. R. Acad. Cien. y Artes Barcelona*, 3. ser., 11 (1914), No. 21, pp. 18).—This is an inaugural address reviewing some recent progress in methods of studying meteorological problems.

Climatological data for the United States by sections (*U. S. Dept. Agr., Weather Bur. Climat. Data*, 2 (1915), Nos. 5, pp. 238, pls. 2, figs. 8; 6, pp. 226, pls. 2, figs. 7).—These numbers contain, respectively, brief summaries and detailed tabular statements of climatological data for each State for May and June, 1915.

Annual report of the Iowa Weather and Crop Service for 1914, G. M. CHAPPELL (*Iowa Yearbook Agr.*, 15 (1914), pt. 11, pp. 747-794, figs. 2).—This is "a condensed summary of the monthly and weekly bulletins issued by the Iowa Weather and Crop Service in cooperation with the Weather Bureau of the U. S. Department of Agriculture. . . ."

"The mean temperature for the State was 49.1° F., or 1.7° higher than the normal. . . . The highest temperature reported was 109° at Centerville, Appanoose County, on July 12. The lowest temperature reported was -31° at Iowa Falls on December 26. . . . The average amount of rainfall and melted snow for the year was 31.93 in., or 0.04 in. less than the normal, and 1.98 in. more than the average for 1913. The greatest amount at any station was 44.11 in., at Marshalltown, Marshall County, and the least amount was 23.32 in. at Columbus Junction, Louisa County. The greatest monthly precipitation was 16.24 in. at Lenox, Taylor County, in September. . . . The average amount of snowfall was 27.5 in. The greatest amount reported from any station was 50.7 in. at Northwood, Worth County, and the least amount was 14.9 in. at Monroé, Jasper County. . . . The prevailing direction of the wind was south. The greatest velocity reported was 68 miles per hour from the northwest at Sioux City on February 28. The average number of clear days was 166; partly cloudy, 102; cloudy, 97, as against 182 clear days, 89 partly cloudy, and 94 cloudy days in 1913. More than the normal amount of sunshine was experienced."

As regards crop production, the year was characterized by a deficiency of rainfall during the growing season. "The hot, dry weather during July and August greatly reduced the yield of corn, especially in the southern counties, where the effects of the drought were even worse than in 1913."

The weather of the past agricultural year, F. J. BRODIE (*Jour. Roy. Agr. Soc. England*, 75 (1914), pp. 117-124).—The means and extremes of temperature, rainfall, and sunshine for 1914 and for long series of previous years in different

districts of England and Wales are summarized in tables and discussed as usual with reference to agricultural conditions. The annual and average rainfall (1904-1914) at different places in the United Kingdom are also tabulated. It is stated that agriculturally the most notable feature of the weather of the year was the irregularity of the rainfall. Nevertheless "the crops were on the whole in excess of the average."

The weather of 1914, D. A. GILCHRIST (*County Northumb. Ed. Com. Bul. 22 (1915), pp. 95-101*).—The rainfall during 1914 at the Cockle Park Experiment Station is compared with that of previous years and other regions of England.

The rainfall at this place was 30.7 in., or 1.75 in. above the 17-year average. The number of rain days was 199. The heaviest rainfall (4.26 in.) was in December; the lightest (0.61 in.) in April. Data are also given for pressure, temperature of air and soil (see p. 510), summer frosts (1898-1914), humidity, cloudiness, wind, etc. The mean temperature for the year was 47.3° F.; the maximum, 77.2°, June 30; the minimum 24.4°, December 21. Frost temperatures on the grass were recorded as late as June 1 and as early as September 22.

The weather of Scotland in 1914, A. WATT (*Trans. Highland and Agr. Soc. Scot., 5. ser., 27 (1915), pp. 341-354*).—"This report consists of (1) a general description of the weather over the Scottish area from month to month; (2) a selection of rainfall returns, in which each county in Scotland is represented by one or more stations. . . .

"The outstanding feature of the year as regards weather was the more or less general prolonged shortage of rain from the middle of April to the end of October. At the end of October the total rainfall for the first ten months of 1914 was, as a rule, much below the normal, but the heavy rains of November and December brought about in various inland and western districts an excess for the whole year. In eastern districts there was a fairly well-defined deficiency."

Meteorological observations in Moscow during 1913-14, E. LEYST (*Bul. Soc. Imp. Nat. Moscou, No. 4 (1913), pp. 616-664; n. ser., 28 (1914), pp. 279-327*).—Data for atmospheric pressure, temperature of the air and soil, radiation, humidity of the air, cloudiness, duration of sunshine, precipitation, direction and force of the wind, and miscellaneous optical and electrical phenomena are summarized and briefly discussed.

Meteorological observations (*Ann. Statis. Egypte, 6 (1914), pp. 9-19*).—This article contains a brief note on the meteorological service of Egypt, and summarizes the available reliable records of observations on pressure, temperature, humidity, rain days, and nilometer readings at different places in Egypt up to and including 1913. Some of the records run back to 1868.

On the climate of the principal rubber producing countries, W. VAN BEMMELEN (In *International Rubber Congress met Tentoonstelling, Batavia, Sept., 1914. Rubber Recueil, Amsterdam: J. H. de Bussy [1915], pp. 145-166, pl. 1*).—This article describes the climate of the Amazon and Congo basins, Ceylon, Malacca, Sumatra, Borneo, and Java.

It is stated in general that "the climate of these countries is purely tropical; that is to say, warm, damp, and equable. The temperature in the plains is 25 to 27° C., declining above the sea level at the rate of about 0.6° for every 100 meters. The percentage of moisture in the air is great, and as a result the pressure of aqueous vapor is proportionately high (± 20 mm.) and the rainfall is more than abundant (2,000 mm. and more per year); above all, however, its evenness is the most conspicuous feature of the climate. The yearly rise and fall in temperature amounts to only a few degrees and the daily difference far exceeds the yearly, though even that is not excessive. Periods of drought are seldom of longer duration than two months. The force of the wind is slight,

storms are practically unknown; there are merely the gusts which are forerunners of the many thunderstorms and can be pretty violent."

Temperature in cultivated and uncultivated soil, and influence of good cultivation, D. A. GILCHRIST (*County Northumb. Ed. Com. Bul. 22 (1915), pp. 97, 98*).—Observations in adjacent plats cultivated to a depth of 2 in. and uncultivated showed a more even temperature in the former at a depth of 1 ft. At a depth of 4 ft. there was no appreciable difference. The uniformity of temperature in the cultivated soil is attributed to its higher water content.

The rains of the Nile basin and the Nile flood of 1912, J. I. CRAIG (*Survey Dept. Egypt Paper 32 (1914), pp. 104, pls. 7*).—Observations similar to those of previous years (E. S. R., 30, p. 511) are included in this report. The last chapter contains an extension of the known equation of continuity for a river to include the effects of seepage, evaporation, and rainfall, and applies the theory to calculate the losses on the White Nile between Malakal and Omdurman in the beginning of 1912.

SOILS—FERTILIZERS.

Soils of the eastern coal field, S. C. JONES (*Ky. Geol. Survey [Rpt.], 4. ser., 1 (1913), pt. 2, pp. 1067-1078*).—This article discusses the soils of an area of about 10,000 square miles in eastern Kentucky, the topography of which is rough, hilly, and mountainous.

The soils of the area are classed as ridge, hillside, and bottom soils. The ridge soils vary from sand to sandy loams, silt loams, or loams with a clay subsoil. The hillside soils are loams, silt loams, sandy loams, and shale or gravel loams with a yellowish or reddish loam subsoil mixed with sandstone gravel. The first bottom soils consist of brown sandy loams and loams, and the second bottom soils of loams and silt and clay loams, varying in color from gray to yellow and brown.

Chemical analyses by the state experiment station of soils from different counties in the area show that the soils of the upper coal measures "contain on an average about twice as much total nitrogen, total phosphorus, and total potassium as the lower coal measures soils. Also, they contain a much larger amount of soluble phosphorus and potassium." The bottom lands are all acid and contain much less total nitrogen and soluble phosphorus and potassium, due, it is stated, to long cultivation without any system of crop rotation."

Soil survey of Webster County, S. C. JONES (*Ky. Geol. Survey [Rpt.], 4. ser., 1 (1913), pt. 2, pp. 1079-1107*).—This report deals with the soils of an area of 214,400 acres in western Kentucky, the topography of which is divided into low flat bottoms, undulating or gently rolling upland, and broken or hilly upland. With reference to origin, the soils are residual and transported, the former occupying the upland soils and comprising 135,680 acres and the latter, the bottom lands, comprising 78,720 acres.

Five soil types are recognized, of which the yellow silt loam of the hilly and undulating lands predominates. Mechanical and chemical analyses (the latter by the state experiment station) of each type are reported. "Both the crop yields and chemical analyses indicate a lack of plant food in all these soils with the exception of the dark brown clay loam." The soils are more abundantly supplied with potassium than with either phosphorus or nitrogen. A large portion of the bottom soils need drainage.

Pot experiments with a soil similar to the yellow silt loam of this county showed that "on the whole, phosphorus decidedly increased the yields of wheat, oats, and clover, but not that of tobacco. Nitrogen decidedly increased the yields of wheat, oats, and tobacco, but not that of clover. Potassium moderately increased the yields of wheat and oats and slightly increased that of

clover, but did not have a marked effect on that of tobacco. Rock phosphate used alone gave consistent gains except with tobacco. Used with manure, however, its effect seems to have been negative." Limestone alone produced a moderate increase with oats and clover and with tobacco following clover; used with phosphorus on clover there was a decided increase over that resulting from phosphorus alone.

Soil survey of the Marrs farm, S. C. JONES (*Ky. Geol. Survey [Rpt.]*, 4. ser., 1 (1913), pt. 2, pp. 1109-1118).—This report deals with the soils of a farm of 300 acres in the northwestern part of Henderson County, Ky. The topography consists of rolling uplands and flats or bottom lands. The natural drainage of the flats and parts of the upland is poor.

It is stated that the soils are probably largely of transported origin. These are described in three types which are, in the order of area, yellow silt loam, gray clay loam, and gray silt loam. Chemical analyses made at the Kentucky Experiment Station show the soils of this farm to be poor in total nitrogen and phosphorus and rich in total potassium. All of the soils are more or less acid.

Lining and the use of leguminous green manures and rock phosphate are suggested for these soils.

Soil surveys of the Hartford, Madisonville, and Central City quadrangle, S. C. JONES (*Ky. Geol. Survey [Rpt.]*, 4. ser., 1 (1913), pt. 2, pp. 1119-1132).—This report is in two parts.

The first part deals with the soils of the Hartford quadrangle, an area of 158,080 acres in the western coal field of Kentucky, the topography of which is divided into low flat bottoms, gently rolling upland, and broken hilly land. The soils are of residual and transported origin, the former occupying the upland and the latter the bottom land. Five soil types are recognized, of which the yellow silt loam predominates, covering more than half the entire area.

The second part deals with the Madisonville and Central City quadrangles, which cover an area of 316,160 acres in the central part of the western coal field. The topography is divided into bottom lands, rolling upland, hilly areas, and high flat ridges. The soils are of residual and transported origin and are classed as yellow silt loam, which occupies the undulating and hilly areas, gray silt loam, and low flat bottom soils. The first is the most extensive.

Soils of Meade and Breckinridge [Counties], S. C. JONES (*Ky. Geol. Survey [Rpt.]*, 4. ser., 1 (1913), pt. 2, pp. 1139-1156).—This report deals with the soils of an area in northwestern Kentucky which comprises two counties, the topography of which is rather diversified.

The soils are derived mainly from sandstone and limestone. The soils of the limestone region are mainly residual. The surface soil to a depth of 6 or 8 in. varies from yellowish or reddish loam to reddish or yellowish fine sandy loam with a reddish clay loam subsoil. The sandstone soils are rather uniform, the surface layer to a depth of 6 or 8 in. varying from a gray to a light brown fine sandy loam which is very loose in texture, has a poor moisture-holding capacity, and usually has a low content of organic matter. The subsoil is a yellow fine sandy material containing considerable clay. Chemical analyses of both types of soil showed them to be relatively rich in potassium and poor in nitrogen and phosphorus.

The results of analyses and pot culture experiments with different fertilizers indicate that the most practical method of improving these soils is to use leguminous green manures, lime, and rock phosphate, and to prevent soil washing.

The soils and agriculture of the southern New York highland region, E. O. FIPPIN (*Cornell Countryman*, 12 (1915), No. 7, pp. 578-584, 600, 602, figs. 3).—This article deals with the soils and agriculture of an area of 15,000 square

miles in southern New York, comprising twenty-seven counties, the topography of which varies from hilly to mountainous.

The soils are mainly of glacial and alluvial origin. Four series of glacial soils are discussed, of which the Volusia series predominates outside of the Catskill region. Of the water deposited types the valley terrace and first bottom soils are discussed. It is stated that the poorer of these soils need liming, proper subsoil drainage, and the addition of organic matter.

Soils from the East Africa Protectorate (*Bul. Imp. Inst. [So. Kensington], 12 (1914), No. 4, pp. 515-540*).—Mechanical and chemical analyses of samples of 24 soils from the land bordering the Juba River in East Africa are reported.

Most of the soils were of a clayey character, had good moisture retaining powers, and contained adequate quantities of calcium carbonate. The content of mineral plant food constituents is considered adequate in all cases except one, but nitrogen deficiencies occurred in certain cases. All the soils contained alkaline carbonates and also sodium chlorid and sulphates in smaller quantities. Calcium sulphate sometimes accompanied sodium carbonate.

On rubber soils, E. C. J. MOHR, (In *International Rubber Congress met Tootoonstelling, Batavia, Sept., 1914, Rubber Recueil, Amsterdam: J. H. de Bussy [1915], pp. 167-170*).—The principal characteristics of soils of various rubber-producing regions, but especially those of the east coast of Sumatra, are described. No attempt is made to define sharply types of soil best suited to rubber trees, but it is pointed out that such soils should, as a rule, have high water holding, percolation, and capillary capacities, insuring an abundant water supply to the plant. The larger proportion of the rubber (and tobacco) soils of Sumatra are sandy and vary widely in chemical composition.

The acidity of Malayan soils, M. BARROWCLIFF (*Agr. Bul. Fed. Malay States, 3 (1914), No. 2, pp. 45-50*).—Estimations of the lime requirements of Malayan soils taken over extensive areas, using the method of Bizzell and Lyon (E. S. R., 30, p. 422) with a slight modification, showed that inland undulating land has an acidity corresponding to 2 to 3 tons of lime per acre, while the clays and peaty clays found near the west coast require from 5 to 6½ tons to produce neutrality. These results are taken to indicate that liming treatment as hitherto advocated is totally inadequate. "The figures . . . show plainly the efficiency of limestone as a neutralizing agent and its employment in preference to lime can be unhesitatingly recommended."

It is further noted that the soils on which the best coconut growth in the country is obtained have an acidity equivalent approximately to 6 tons of lime per acre-foot.

Reference is made to previous work by Hutchinson and MacLennan (E. S. R., 32, p. 32).

The inundation of the valley of the Yser, BAROIS (*Bul. Soc. Nat. Agr. France, 75 (1915), No. 2, pp. 174-181*).—It is thought that the inundation of the valley of the Yser as a war measure will result in a compacting of the agricultural soils, a diminution of aeration, and a deposit of marine salts in the surface soils.

Agricultural chemistry and vegetable physiology, N. H. J. MILLER (*Ann. Rpts. Prog. Chem. [London], 11 (1914), pp. 213-237*).—Investigations during 1914 relating mainly to soils and plant nutrition are reviewed as usual. It is stated that "although for the year 1914 no results of exceptional importance have to be recorded, a number of investigations of considerable interest relating to soils and plant nutrition have been carried out. The soil problems which have received most attention are those connected with partial sterilization, absorption of bases, acidity, and the production and movements of nitrates

in soils, while in the case of plant nutrition a good deal of attention continues to be given to the question of stimulants."

Soil problems, J. W. LEATHER (*Rpt. Agr. Research Inst. and Col. Pusa, 1913-14, pp. 16-18*).—In continuation of investigations (E. S. R., 22, p. 20) on the relations existing between the amount of carbon dioxid in soils and the amounts of lime and magnesia in solution, it was found that if magnesium carbonate is present in more than very small quantities, calcium carbonate becomes practically insoluble. Dolomite was found to dissolve as a double salt in carbon dioxid, but the presence of either calcium carbonate or magnesium carbonate was found to protect the dolomite from the action of the carbon dioxid. "This work has shown that no fertile soil can contain material proportions of magnesium carbonate, for if it did, the lime would become practically insoluble and the plant would die of lime starvation."

Analyses of samples of the alluvial soils from the lands irrigated by the upper and lower Swat River canals in India indicated that the lime content varies from high to low, potash is abundant, and there is an occasional deficiency in available phosphoric acid and a general deficiency in organic nitrogenous matter.

The movement of soluble salts with the soil moisture, F. S. HARRIS (*Utah Sta. Bul. 139 (1915), pp. 119-124, figs. 2*).—Experiments with small sections of soil containing various quantities of soluble salts and through which water was passed horizontally and vertically are reported, the purpose of the experiment being to determine the movement of salts with water through the soil.

The results indicate that soluble salts in the soil very readily move horizontally and vertically with the current of soil moisture. It was found that salts moving horizontally with the soil moisture accumulated at the end of the test tank where evaporation took place, and that in general the salts increased in the soil from the end where water was added to the other end. The upward movement of salts and their accumulation at the surface were especially marked in soils containing a large amount of salt. It is concluded in general from these experiments that "lowlands will continue to be ruined by the accumulation of alkali salts as long as the uplands are overirrigated."

The rôle of colloids in agricultural soil, L. G. DEN BERGER (*Teysmannia, 24 (1913), Nos. 7, pp. 438-450; 8-9, pp. 512-520; 11-12, pp. 689-701; 25 (1914), Nos. 1, pp. 45-53; 2, pp. 65-67; 3, pp. 145-152; 5-6, pp. 251-255*).—This article describes the common properties of colloids, particularly their powers of absorption, and discusses the soil colloids in some detail, with particular reference to their origin and influence under different conditions on the physical, chemical, and biological properties of soils and on plant growth.

Some data on the question of the form of nitrogen in the soil, A. SHMUK (*Zhur. Opytn. Agron. (Russ. Jour. Expt. Landw.), 15 (1914), No. 2, pp. 139-153, figs. 2; abs. in Chem. Abs., 9 (1915), No. 7, p. 946; Zentbl. Agr. Chem., 44 (1915), No. 1, p. 9*).—Investigations are reported which indicate that the distribution of amid compounds in podzol and chernozem soils is much the same as in protein. While the ratio of proteid nitrogen to the total organic matter of soils varied widely, the ratio to total nitrogen was quite similar in all tests. Podzol soil was found to contain a considerable proportion of water-soluble amid compounds. The distribution of different forms of nitrogen was quite similar in chernozem and podzol soils, but was quite different from that observed in the case of laterite soil.

Soil bacteriology, C. M. HUTCHINSON (*Rpt. Agr. Research Inst. and Col. Pusa, 1913-14, pp. 81-88*).—This is a brief review of investigations which have already been noted in part from other sources (E. S. R., 31, pp. 722, 731).

In continuation of studies of ammonification and nitrification of green manures, 14 species of bacteria were identified as apparently closely connected with the decomposition of buried Sann hemp, and their physiological and morphological characters were studied. No one species of bacteria capable of attacking cellulose was found, although this result was produced by two or more associated bacteria.

The investigations indicated that soil fungi play an important part in breaking down cellular tissue. The fertilizing value of green manures appears to depend upon the rapid formation of simple nitrogen compounds, such as ammonia, from proteid substances. It was found that the nitrification of ammonia "is interfered with by the fact of its concentration and also by the presence of soluble organic substances, some of which, at least, are strongly toxic to nitrifying bacteria and in less measure to others; this condition persists so long as the water extract remains acid to litmus, which under ordinary conditions of manufacture might extend to as much as six weeks. . . . The rapid ammonification which takes place when green manure is placed in water and allowed to ferment was found to be accompanied by the development of large numbers of ciliates, flagellates, and amœbæ, whose presence does not appear in this instance to be prejudicial to the activity of ammonifying bacteria." It was also found "that ammonification is the necessary antecedent to nitrification in the case of organic matter, that this process is furthered by a high percentage of moisture, that high concentrations of ammonia inhibit nitrification, but that such ammonia is absorbed by the soil and can then be nitrified."

The most complete and rapid nitrification was secured "by producing anaerobic conditions with water saturation and subsequently draining and aerating; the rapidity with which nitrification takes place under these conditions depends upon the relative completeness of the anaerobic and subsequently of the aerobic conditions." Under anaerobic conditions produced by water saturation "toxins were produced which not only inhibited nitrification before the ammonia concentration was sufficient to do so but afforded water extracts which were toxic to seedlings and to bacteria; subsequent aeration removes this toxic condition and the formation of nitrates takes place, the ultimate result being a high percentage of nitrification of the nitrogen of the organic matter. . . . In connection with the nitrification of green manure it was found that a loss of nitrate invariably occurred between the eighth and twelfth weeks of the process in the laboratory," but the cause of this was not determined.

Mustard oil cake furnishing nitrogen equivalent to 1 per cent of the dry weight of soil was added to a soil rich in lime without interfering with the normal rate of nitrification. Although the rate of nitrification was in direct proportion to the lime content, it was found that a soil low in lime in time attained the same nitrate concentration as one high in lime.

Azotobacter isolated from various soils showed marked differences in morphological and cultural characters and in nitrogen-fixing capacity. Nitrogen fixation by a pure culture of Azotobacter isolated from Pusa soil "was increased by the additions of basic slag or humus to the ordinary medium, but was diminished by the substitution of magnesium carbonate for calcium carbonate. . . . The addition of a seer [2.057 lbs.] of cane sugar to a plat 2 sq. yds. in area resulted in an increase, in the nitrogen content of the first 6 in. of soil, of nearly 15 per cent in 10 weeks. . . .

"It was found possible to measure the relative toxicity of various bacterial species to an intermediate form (*Bacillus prodigiosus*) and to one another by use of plate cultures and the measurement of the rate of CO₂ formation in

solid and liquid media, and the effect upon the latter of the antagonism of symbiotic action, as the case might be. Marked instances of antagonism and symbiosis were found, and the production of toxins was demonstrated."

Investigations on protozoa in relation to the factor limiting bacterial activity in soil, T. GOODEY (*Proc. Roy. Soc. [London], Ser. B, 88 (1915), No. B 606, pp. 437-456, figs. 8*).—From the results of further investigations (E. S. R., 25, p. 817) of the Russell and Hutchinson hypothesis (E. S. R., 24, p. 621) it is concluded that "the protozoa, including ciliates, amœbæ, and flagellates added to the soil have not been able to act as a factor limiting bacterial activity in the soil. Inferentially, therefore, the ciliates, amœbæ, and flagellates obtainable from ordinary soil under cultural conditions do not function as the limiting factor."

Further investigations on the biological absorption of phosphoric acid in the soil, A. DUSHECHKIN (*Zhur. Opytn. Agron. (Russ. Jour. Expt. Landw.), 15 (1914), No. 6, pp. 467-500, figs. 6; abs. in Chem. Abs., 9 (1915), No. 8, p. 1085*).—In further studies of the biological absorption of phosphoric acid in soils (E. S. R., 27, p. 216), the experiments were extended to include the effect of water content and light and to determine the connection between denitrification and phosphoric acid absorption.

It was found that the biological absorption of phosphoric acid in soils increased with increasing water content. With time, decomposition products accumulated in the soil which had a dissolving effect on the phosphoric acid and diminished the absorption process. Nitrate additions increased the phosphoric acid absorption only with medium moisture content (25 per cent). The absorption was most marked under conditions favoring denitrification. With a higher moisture content (35 per cent) it was stronger in light, but with a lower moisture content (25 per cent) it was favored by darkness.

The comparative effect of phosphates and sulphates on soil bacteria, E. B. FRED and E. B. HART (*Wisconsin Sta. Research Bul. 35 (1915), pp. 35-66, figs. 6*).—Investigations on the influence of phosphates and sulphates in the form of chemically pure salts upon the activities of soil bacteria, as measured by rates of ammonification with pure and mixed cultures in soil and solution, by rates of carbon dioxide evolution, and by plate counts to determine if the fertilizing effect of these substances can be explained in part by the promotion of bacterial action are reported. The soil used was Miami silt loam.

It was found, in general, that the addition of mineral fertilizers to soils caused an increase in ammonification, carbon dioxide evolution, and total number of bacteria. Monobasic potassium phosphate, precipitated calcium phosphate, and the sulphates of potassium and calcium all increased ammonification in solution more or less, while tricalcium phosphate was ineffective. The action of monobasic potassium phosphate as compared with that of potassium sulphate is taken to indicate that the potassium ion does not materially influence ammonification. Monobasic potassium phosphate caused an enormous increase in numbers of bacteria in solution, followed by a rise in ammonia production, which was not, however, in proportion to the number of bacteria.

All the phosphates used increased the number of soil bacteria, particularly dibasic potassium phosphate. Dibasic potassium phosphate and tricalcium phosphate also stimulated ammonification in soil. Calcium sulphate, potassium and calcium phosphates, and ammonium, magnesium, and potassium sulphates all stimulated more or less the evolution of carbon dioxide from the soil.

"The results of this work, as a whole, suggest that possibly the increased crop production of a soil resulting from the application of soluble phosphates is in part due to the promotion of bacterial activity. . . . The sulphates, although

as low in amount in most soils as the phosphates, will not, in all probability, have the same general crop-producing power as the phosphates."

A new case of unproductiveness in sugar cane soils, F. LEDEBOER and A. E. BERKHOUT (*Arch. Suikerindus. Nederland. Indië*, 22 (1914), No. 18, pp. 653-672, pl. 1; *Meded. Proefstat. Java-Suikerindus.*, 4 (1914), No. 26, pp. 521-540, pl. 1; *abs. in Internat. Inst. Agr. [Rome], Mo. Bul. Agr. Intel. and Plant Diseases*, 5 (1914), No. 8, p. 1000; *Internat. Sugar Jour.*, 16 (1914), No. 190, p. 486; *Jour. Soc. Chem. Indus.*, 33 (1914), No. 21, p. 1066).—A case of unproductiveness in certain so-called white clay sugar cane soils in the Residency of Pelsalongan in Java is reported.

Chemical analyses show these soils to be relatively poor in nitrogen and phosphoric acid but to contain relatively large percentages of sodium carbonate (as much as 0.321 per cent), to which their unproductiveness is mainly attributed. Pot culture experiments with these soils using physiologically acid reacting fertilizers, lime, and stable manure in different combinations showed that complete fertilization with lime and the addition of ammonium sulphate with lime produced better cane crops than complete fertilization without lime or the addition of ammonium sulphate and stable manure.

While ammonium sulphate, potassium sulphate, and double superphosphate apparently neutralized the extreme alkalinity of the soil and supplied the lacking plant food, the chief benefit is attributed to the liming, owing to its favorable effect on the soil structure.

The soils containing the carbonate puddle badly after rains. The addition of 1.2 per cent of quick lime greatly improved the soil, and an application of 3.6 per cent of lime, while injuring vegetation, completely deflocculated the soil. Applications of gypsum produced still better results. The subsoil water was found to be very rich in sodium carbonate and is apparently the source of this substance in the soil.

A practical way to supply plant food to our soils, S. C. JONES (*Ky. Geol. Survey [Rpt.]*, 4, ser., 1 (1913), pt. 2, pp. 1133-1138).—The results of pot culture experiments carried on at the Kentucky Experiment Station on two soils, a red loam and a gray fine sandy loam, are reviewed. They indicate "that for general farm practice in which such crops as corn, wheat, oats, and tobacco are grown, a profit may be obtained from an increase in the nitrogen and phosphorus content in the average soils of the State." The use of leguminous green manures and rock phosphate is recommended as being the most practicable method of supplying the needed plant food.

The composition and value of farm manures, O. F. JENSEN (*Michigan Sta. Circ.* 25 (1915), pp. 3-7).—Data are compiled from various sources to show the composition and value of farm manures. It is stated that sheep, hog, and hen manures are more valuable than other manures because of the great proportions of concentrates fed.

Experiments with barnyard manure at Darmstadt, P. WAGNER (*Mitt. Deut. Landw. Gesell.*, 30 (1915), Nos. 4, pp. 41-44; 5, pp. 52-55).—Some of the more important results of twelve years' experiments with manure and fertilizers are summarized in this article, with special reference to the decline of yield without manure, plant food removed by crops on manured and unmanured soil, the possible increase and cost of increase of yield with commercial fertilizers, the relation of plant food applied to the needs of the plant and requirements of the soil, the amount and cost of the increased yield with barnyard manure, the practical value of manure as compared with its fertilizing effect, and the fertilizing action of the different constituents of manure.

The sandy soil used in these experiments contained 0.077 per cent of nitrogen, 0.072 per cent of acid-soluble phosphoric acid, 0.214 per cent of total phosphoric

acid, 0.05 per cent of acid-soluble potash, and 1.96 per cent of total potash. The yield of potatoes on this soil without fertilizer or manure declined more than three-quarters in eleven years, and of rye more than one-half in twelve years. With a rotation of potatoes, rye, and beets without manure there was removed from the soil in twelve years 131.25 lbs. of phosphoric acid per acre, 329.65 lbs. of potash, and 334.64 lbs. of nitrogen. When the soil was fertilized with combinations of two of the essential fertilizer constituents the amounts removed by the crops were 566.94 lbs. of phosphoric acid, 1,453.76 lbs. of potash, and 1,156.76 lbs. of nitrogen. It was found that the phosphoric acid and potash of manure was better utilized than that of Thomas slag and potash salts, and this was especially marked during the first years of the experiments.

Bat guanos, P. L. GILE and J. O. CARRERO (*Porto Rico Sta. Rpt. 1914, p. 16*).—Brief reference is made to vegetation tests which have been undertaken to determine the availability of the phosphoric acid in the bat guanos of Porto Rico.

“The work accomplished so far shows that these deposits vary greatly in chemical composition, but that there are several more or less well-defined types. The vegetation tests show that the availability of the phosphoric acid also varies greatly.

“These deposits appear quite numerous and well distributed over the island. There is probably no doubt but that the deposits can furnish valuable fertilizing material for certain districts of the island. The individual deposits, however, are probably too small and transportation on the island too costly for the guanos to be exploited on any scale commercially.”

Fertilizer experiments on the red clay soil, P. L. GILE and J. O. CARRERO (*Porto Rico Sta. Rpt. 1914, p. 14*).—It is stated that the results of these experiments showed that lime, sodium nitrate, ammonium sulphate, dried blood, a nitrogenous and phosphatic fertilizer, and a complete fertilizer all failed to increase appreciably the yield of cane on this soil.

Drill fertilizing, TACKE (*Mitt. Dcut. Landw. Gesell., 30 (1915), No. 9, pp. 118, 119*).—In experiments with rye, drilling fertilizers showed little advantage over broadcasting.

Production of nitrates from air, with special reference to a new electric furnace, E. K. SCORR (*Jour. Soc. Chem. Indus., 34 (1915), No. 3, pp. 113-126, figs. 10; rev. in Elect. Rev., 76 (1915), No. 1941, pp. 166, 167; Engin. Mag., 49 (1915), No. 1, pp. 104, 105, figs. 2*).—The author describes and explains the operation of his combined three-phase current furnace for the oxidation of the nitrogen of the air, and shows why he believes it will considerably increase the present yields of nitrogen compounds from this source.

Potassium from the soil, C. G. HOPKINS and J. P. AUMER (*Illinois Sta. Bul., 182 (1915), pp. 3-10, figs. 2*).—Five years' pot experiments with clover and rape on a brown silt loam and on the so-called insoluble residue obtained from digestion of the brown silt loam for ten hours with boiling hydrochloric acid, having a specific gravity of 1.115, are reported, the main purpose of which was to determine the extent to which decaying organic matter is able to liberate soil potassium.

The results indicate that after two years' green manuring sufficient potassium was liberated from the insoluble residue to enable clover to be benefited by lime and phosphate fertilizers so as to exceed the yield of crops on the normal soil to which no such fertilizers had been added. The clover hay produced on the normal soil contained about three times as much potassium per gram as was contained in crops from the insoluble residue, which is taken to indicate that the actual requirement of clover for potassium may be very much less than has been estimated from the composition of hay grown on ordinary soils. It

is also thought that the results support the theory that the benefit sometimes produced by potash fertilizers when applied to soils very deficient in decaying organic matter may be due in part to the power of the soluble potash salt to increase the availability of phosphorus and other elements.

Salines in the Owens, Searles, and Panamint basins, southeastern California, H. S. GALE (*U. S. Geol. Survey Bul. 580-L (1914), pp. VI+251-323, pls. 3, figs. 31; abs. in Amer. Fert., 42 (1915), No. 8, pp. 42-51, figs. 3*).—This is a preliminary report summarizing the history of the saline deposits of these basins, which are believed to have been produced by the concentration and ultimate disappearance of "waters that formerly filled Owens Valley until they overflowed, flooding successively lower and lower basins, and forming for a time a chain of large lakes in what is now the desert region of southeastern California." "These flood waters passed from Owens Valley, the principal source of the water supply, through Indian Wells, Searles, and Panamint valleys, in each of which there was an extensive lake. Finally the waters are believed to have overflowed also into Death Valley. . . . It is the purpose to point out in the present paper the more salient distinguishing features and relations of these several basins and to suggest interpretations that may be placed on their influence in saline deposition."

It is estimated that the Searles Lake deposit contains 4,000,000 tons of water-soluble potash salts. In six analyses of brine from Searles Lake reported in this bulletin, the potassium varied from 5.54 to 7.27 per cent. Searles Lake is thought to offer the most promising prospect of commercial production of any of the localities so far examined for potash deposits. The author is of the opinion, however, "that commercially valuable concentrations of potash are not to be looked for in the desert-basin deposits generally. In the first place, salines deposited by shallow, intermittent lakes are not only so mixed with muds as to render their profitable recovery very doubtful, but such deposits are unlikely to retain on a large scale any considerable percentages of potassium in the soluble form. Only in the basins where large and deep saline lakes have existed and dried up under favorable conditions are massive deposits of saline free from mixture with mud to be looked for. Such conditions are rather exceptional. Probably few desert saline lakes have in fact dried up so free from the mixture of clay or other sediments that their water-soluble salts have retained the major portion of the potash originally present in the lake water.

"The confident hope is still held out that these exceptional conditions exist in some places and that by good fortune or otherwise they may be revealed. It seems that in Searles Lake one such exceptional place has been found, and it is possible that there may be even larger and more valuable deposits still to be discovered."

German potash situation, J. G. LAY (*U. S. Dept. Com., Com. Rpts., No. 76 (1915), p. 10*).—The authorized deliveries of potash for domestic and foreign consumption during 1915 are given. These amount to 948,800 metric tons of potash (K_2O) as compared with 1,166,600 metric tons for 1914. It is stated that plans for denaturing potash salts so that the embargo can be removed have not yet materialized and the embargo, therefore, still remains in force.

The phosphate deposits of South Carolina, G. S. ROGERS (*U. S. Geol. Survey Bul. 580-J (1914), pp. 183-220, pl. 1, figs. 2; abs. in Amer. Fert., 42 (1915), No. 2, pp. 37-49, fig. 1*).—The history, character, distribution, amount available, methods of mining, present status, and future prospects of these phosphates are discussed.

It is shown that production has fallen off greatly within the last few years. In 1912 it was only 131,490 tons, or about that of the period between 1875 and 1880. While the prospects of a marked revival of mining operations in this

field are considered to be poor, attention is called to the fact that there is probably at least 5,000,000 tons of 60 per cent phosphate still available which improved machinery may at some later time render workable. The highest grade of rock that the field can be expected to produce, however, does not average more than 61 per cent phosphate containing, as a rule, more than 3 per cent iron and alumina.

A briefer report on these deposits has been noted (E. S. R., 30, p. 27).

Solubility of the different constituents of slag, M. SIROT and G. JORET (*Jour. Agr. Prat., n. ser., 27 (1914), No. 25, p. 787; abs. in Chem. Abs., 9 (1915), No. 5, p. 684*).—It is shown that citric and malic acids have greater solvent power for the constituents of basic slag than do tartaric, acetic, lactic, and oxalic acids. All of the constituents of the slag, including silicon, phosphoric acid, calcium, magnesium, sulphates, iron, and manganese, were found to be soluble in the weak acids, the solubility varying with the fineness of the slag and the actual solubility of the salts formed. The author concludes that slag is not simply a phosphatic fertilizer but that it contains many other substances useful to plants in forms very soluble in weak organic acids.

The solubility and assimilability by plants of the water insoluble-phosphoric acid or superphosphate prepared from Kostroma phosphates, P. KOSOVICH (*Zhur. Opytn. Agron. (Russ. Jour. Expt. Landw.), 15 (1914), No. 6, pp. 501-538, figs. 5*).—Superphosphate containing about 11 per cent of phosphoric acid soluble in water and 3½ per cent almost completely soluble in Peterman's reagent (ammonium citrate) made from low-grade phosphate (containing from 20 to 24 per cent of phosphoric acid) was tested in pot experiments with oats and mustard on sand and chernozem soil. The citrate-soluble phosphoric acid appeared to be not less than half as valuable as the water-soluble for fertilizing purposes.

A new theory regarding the feeding power of plants, E. TRUOG (*Science, n. ser., 41 (1915), No. 1060, pp. 616-618*).—As a result of his own investigations and those of others, the author formulates the hypothesis that "plants containing a relatively high calcium oxid content have a relatively high feeding power for the phosphorus in raw rock phosphate. For plants containing a relatively low calcium oxid content the converse of the above is true."

Within the meaning of this hypothesis "a calcium oxid content of less than 1 per cent may be considered relatively low. Corn, oats, rye, wheat, and millet belong to this class. A calcium oxid content of somewhat more than 1 per cent may be considered relatively high. Peas, clover, alfalfa, buckwheat, and most of the species of the Cruciferæ belong to this class."

The explanation offered for this hypothesis is that, with plants having a high capacity for assimilating lime, the calcium bicarbonate formed by the action of carbonic acid on tricalcium phosphate will be readily absorbed along with the dicalcium form and thus permit the continued action of the carbonic acid on the insoluble phosphate. On the other hand, with plants having a low assimilative power for lime, the reaction between carbonic acid and tricalcium phosphate soon reaches a state of equilibrium, and soluble phosphate ceases to be produced. The hypothesis is based upon the general theorem that the feeding power of a plant for an insoluble substance depends "(1) on the solubility of that substance in carbonated water and (2) on whether or not the plant removes from solution all the products of the solubility reaction in the proper proportion so as to allow the solubility reaction to continue indefinitely."

Chlorosis of sugar cane, P. L. GILE and J. O. CARRERO (*Porto Rico Sta. Rpt. 1914, pp. 14, 15*).—Tests on the effect of ferrous sulphate and stable manure on the development of chlorotic cane showed that small applications of these mate-

rials had but little effect on the cane. Heavier applications seemed to produce quite notable increases in tonnage but at a prohibitive cost.

Lime-induced chlorosis, P. L. GILE and J. O. CARRERO (*Porto Rico Sta. Rpt. 1914, pp. 15, 16*).—Brief reference is made to experiments with rice similar to and in extension of previous experiments with pineapples (E. S. R., 26, p. 121; 31, p. 816). In these experiments an attempt was made to determine whether the action of calcium carbonate in inducing chlorosis is due solely to its depressing effect upon the assimilation of iron.

When ferrous sulphate was applied to chlorotic rice grown in calcareous soils it was found that "the results were similar to those obtained in previous work with pineapples. Ferrous sulphate applied to the leaves as a spray restored the green color and induced a normal growth, but applied to the soil was without effect."

Various other experiments bearing on the causes of chlorosis are referred to as in progress but no results are reported.

The purification of waste liquors from paper mills, G. B. KERSHAW (*Surveyor, 47 (1915), No. 1199, pp. 28-30*).—The author states that in the treatment of waste waters from paper mills large amounts of sludge are obtained which may be used for manuring purposes as it contains considerable lime.

Commercial fertilizers, W. J. JONES, JR., ET AL. (*Indiana Sta. Bul. 180 (1915), pp. 407-520*).—This bulletin gives the results of the fertilizer inspection, including analyses and valuations of 1,420 samples collected in Indiana during the spring and fall of 1914. A list of brands registered since May 15, 1914, and brands previously registered, to be on sale in 1915, and other data are also given.

Analyses of commercial fertilizers, P. H. WESSELS ET AL. (*Rhode Island Sta. Insp. Bul., 1914, Sept., pp. 2-8*).—This bulletin contains analyses and valuations of 50 samples of high-grade fertilizers and fertilizing materials collected in Rhode Island during the spring of 1914. It is stated that nearly two-thirds of the total number of brands listed fell below their guaranties as regards water-soluble phosphoric acid and about one-half are deficient in available phosphoric acid.

Analyses of commercial fertilizers, P. H. WESSELS ET AL. (*Rhode Island Sta. Insp. Bul., 1914, Oct., pp. 3-11*).—This bulletin contains analyses and valuations of 21 samples of limes and wood ashes collected in Rhode Island during 1914 and of 33 samples of complete fertilizers not reported in previous bulletins, together with a summary of results for the year. This last indicates that "in 82 per cent of the instances reported the amounts of nitrogen, potash, and total and available phosphoric acid were equal to or above the amounts that were guaranteed, in 9 per cent the amounts were less than 0.3 per cent below the amounts that were guaranteed, and in 9 per cent the amounts were more than 0.3 per cent below the guaranties."

AGRICULTURAL BOTANY.

An experimental study of the rest period in plants: Seeds, W. L. HOWARD (*Missouri Sta. Research Bul. 17 (1915), pp. 58*).—In continuation of other investigations on the rest period of plants (E. S. R., 33, p. 223), the author gives an account of studies carried on with seeds, begun in 1907 and continued for seven years.

In the preliminary tests it was found that seeds of many annual plants were able to germinate while quite immature, but that more than half the species investigated had a pronounced rest period. Of the species having a definite rest period by far the greater percentage are woody plants. The in-

vestigations were continued to determine when the resting phase sets in and whether it can be broken by treatments and what agents are most effective for breaking the rest.

During 1912 and 1913 a study was made of about 100,000 seeds representing about 200 species of plants, and it was found that about 76 per cent had a definite rest period. Where seeds grow at all without rest, germination takes place more quickly in the immature seeds than in mature ones.

In 1912 seeds of a number of species of woody plants were treated to break the rest period. It was found that stratifying these seeds and letting them freeze while in the moist sand proved the best treatment tried for hastening the sprouting and bringing about the highest percentage of germination. Etherizing dried or moist seeds had some beneficial effect on germination, and etherizing seeds that had been stratified and frozen hastened sprouting and also increased the percentage of germination. Etherizing old, dry seeds of herbaceous plants had but little effect on germination and in most instances was found detrimental. Seed corn etherized when dry seemed to be materially benefited. It was found that while corn seed did withstand severe freezing when dry it was badly injured when in a moist or wet condition. Lima beans were found to be severely injured if frozen when dry, and proportionately greater injury was effected if wet. Freezing and etherization were detrimental to watermelon seeds if dry, but they were not injured and in some cases were benefited by freezing, if the seeds were quite moist. Soaking okra seeds had a bad effect on germination, and ether treatments had little or no effect on dry seeds, but were very beneficial to moist or wet ones.

A historical summary and bibliography are appended.

Experiments in forcing native plants to blossom during the winter months, C. O. ROSENDAHL (*Plant World*, 17 (1914), No. 12, pp. 354-361).—Giving an account of attempts to obtain fresh flowers for class use during the winter months, the author states that while the experiments made were not comprehensive enough to form a basis for sweeping conclusions, it has been demonstrated that a considerable portion of the perennials native to the neighborhood of Minneapolis, Minn., lend themselves to successful forcing during winter and that a wealth of fresh material can thus be obtained with comparatively little effort and expense.

The effect of shade on transpiration and assimilation of tobacco in Cuba, H. HASSELBRING (*Estac. Expt. Agron. Cuba Bol.* 24 (1915), pp. 1-33, fig. 1).—The principal conclusions from this work have already been noted (E. S. R., 31, p. 326).

Absorption of ions by plants, F. PLATE (*Atti R. Accad. Lincei, Rend. Cl. Sci. Fis., Mat. e Nat.*, 5. ser., 23 (1914), I, No. 10, pp. 839-844; *abs. in Jour. Chem. Soc. [London]*, 106 (1914), No. 622, I, p. 1039).—*Triticum sativum* and *Hyacinthus orientalis* were grown separately in solutions of the chlorid, bromid, nitrate, and sulphate of manganese. It was found that the anion and cation are utilized in about the same proportion as that which obtains in the solution, the anion going mainly to the shoot and the cation to the root.

The antagonism between ions in the absorption of salts by plants, W. STILES and I. JÖRGENSEN (*New Phytol.*, 13 (1914), No. 8, pp. 253-268).—The authors review briefly the work and opinions of earlier investigators dealing somewhat indirectly, and those of later ones dealing more directly, with antagonism between salts or ions in their absorption from aqueous solutions by plants.

It is considered as evident that this phenomenon is of widespread if not of universal occurrence in organic life. Antagonism appears to be characteristic of cations, not only of nutritive but also of indifferent or poisonous character,

and even between metals and alkaloid bases. It appears to be greatest between ions of different valency, but to be not altogether absent between those of the same valency.

The explanation of antagonism considered as most plausible is that which regards the plasma membrane as a carrier of ions into the interior of the cell by means of reversible combinations with them, the different ions thus interfering with each other's activity in this respect.

A bibliography is given.

Determination of elements necessary to development of maize, P. MAZÉ (*Compt. Rend. Acad. Sci. [Paris], 160 (1915), No. 6, pp. 211-214*).—In continuance of previous studies (E. S. R., 31, p. 221) the author carried out experiments testing the growth of maize in a nutritive solution of given composition, to which some or all of the elements aluminum, boron, fluorin, iodine, and arsenic had been added. The results appear to show that all of the elements named are necessary to the best growth of maize except arsenic, which is distinctly unfavorable to its development.

The chlorosis of plants, P. MAZÉ (*Compt. Rend. Soc. Biol. [Paris], 77 (1914), No. 31, pp. 539-541*).—Summarizing some of his investigations relating to chlorosis (E. S. R., 31, p. 221), the author found that this disease could be induced in maize by a lack of iron, sulphur, manganese, etc. For chlorosis caused by a lack of iron, providing this substance in solution to chlorotic leaves quickly restored their green color. Chlorosis due to a lack of magnesium was less easily controlled, indicating that there are several kinds of chlorosis. The lack of iron is said to be the most common form of the trouble, and this is usually brought about by the presence of large amounts of carbonate of lime in the soil, which check the absorption of iron. Chlorosis due to a lack of manganese is considered to be of a special type, although it too is influenced by alkalinity of soils.

It is said that other alkaline carbonates, as those of potassium and sodium, produce similar effects on the absorption of iron, etc., by plants. Exudation from diseased cells is said to cause chlorosis, and this action is considered to be more or less specific for the different kinds of plants studied.

The influence of fluorin upon vegetation, A. GAUTIER (*Compt. Rend. Acad. Sci. [Paris], 160 (1915), No. 6, pp. 194, 195*).—It is stated that in experiments with fluorin in the nutritive medium it was found that an inhibitive or unfavorable influence was exerted upon very few plants, many more showing an increase of growth, flowering, and bearing, and some showing no effect from fluorin. Mustard gave a ninefold gain as regards seed output under the influence of fluorin, and several other plants named gave analogous results.

Investigations on the resistance of growing plants to hydrocyanic acid fumigation, J. CORTE (*Compt. Rend. Soc. Biol. [Paris], 77 (1914), No. 22, pp. 185-187*).—In order to test the injury by hydrocyanic acid gas fumigation on plants, the author experimented with wheat, castor beans, and garden nasturtiums grown in pots and subjected to different strengths of hydrocyanic acid gas for different periods of time at a nearly uniform temperature of 16° C. (60.8° F.). The gas was generated by the action of dilute sulphuric acid on potassium cyanid. The quantities of potassium cyanid used per cubic meter of space were 12.5, 15.63, 23.25, and 39.06 gm., respectively, amounts which are in excess of those usually recommended for use in fumigation.

Wheat plants were only slightly affected when exposed for one hour to the action of 12 gm. potassium cyanid per cubic meter, and for the complete destruction of the plants a sojourn of two hours exposed to the action of 39 gm. potassium cyanid was required. The castor bean plants showed some lesions where 15 gm. of the cyanid was used per cubic meter, and at 23 gm. the plants suc-

cumbed. The nasturtium plants withstood an exposure to gas from 15.5 gm. of the cyanid for two hours. They appeared to be slightly injured when taken out of the fumigation chamber, but fully recovered vigor in three days.

Action of chloroform and ether on the inversion of saccharose in the roots of sugar beet, P. MAZÉ (*Compt. Rend. Soc. Biol. [Paris]*, 77 (1914), No. 32, pp. 549, 550).—The author states that the immersion of fragments of sugar beet in solutions of chloroform or ether resulted in the excretion of the invert sugar and saccharose into the liquid. Chloroform was found more energetic in this respect than ether. It is believed that chloroform and ether bring about a very abundant secretion of saccharose. The fragments of potatoes submitted to chloroform and ether did not show any saccharification of starch.

Influence of naphthalin on germination, growth, and nitrification in plants, P. CACCIARI (*Staz. Sper. Agr. Ital.*, 47 (1914), No. 5, pp. 347-367).—It was found that when present in from 0.5 to 10 per cent of the seed weight for a considerable period of time naphthalin exerted little or no injurious influence on the germination of wheat and legumes. It was unfavorable to their vegetative development and to their normal rate of nitrification.

The formation of starch in the embryo before the maturity of the seed, A. GUILLIERMOND (*Compt. Rend. Soc. Biol. [Paris]*, 76 (1914), No. 13, pp. 567-571, figs. 12).—From a study of beans, peas, castor beans, and squash seed the author claims that starch is formed in the embryo before the maturity of the seed, and that the chloroplasts in the hypocotyl and cotyledons are formed in the beginning of germination. The plastids formed at the beginning of germination are said to be formed from those which have elaborated starch before the maturity of the seed.

Starch reserve in relation to the production of sugar, flowers, leaves, and seed in birch and maple, F. B. H. BROWN (*Ohio Nat.*, 14 (1914), No. 7, pp. 317-320, figs. 2).—This is a brief preliminary report on species of maple and birch examined in the spring of 1914.

It is stated that before the beginning of bud growth little starch had been utilized, the most pronounced changes being confined to the bark of the stem. During vegetative and floral development in spring, starch utilization involved progressively the branches showing from one to ten annual rings of growth. No marked changes have been noted beyond these portions or in the root.

The origin of anthocyanin in different plant organs, F. MOREAU (*Compt. Rend. Soc. Biol. [Paris]*, 77 (1914), No. 29, pp. 502, 503).—Attention is called to the different manner in which anthocyanin is formed in floral organs and in other portions of plants, but the author claims that in every case it is of a mitochondrial origin.

Anthocyanin formation and mineral nutritive components, A. CZARTKOWSKI (*Ber. Deut. Bot. Gesell.*, 32 (1914), No. 6, pp. 407-410).—The author claims that the production of anthocyanin by young shoots of *Tradescantia viridis* and *T. loekensis* grown in Knop's solution was favored by lowering the content of nitrogen, but of no other single component.

Anthocyanin formation in rose leaves, A. M. LÖWSCHIN (*Ber. Deut. Bot. Gesell.*, 32 (1914), No. 6, pp. 386-393, pl. 1).—The author, having followed up the studies reported by Pensa (*E. S. R.*, 32, p. 428), states that his examinations of young rose foliage leave little room for doubt that not only the filiform, but also the granular elements, serve as a matrix for the production of anthocyanin. It is here synthesized under the influence of the nucleus from the organic materials furnished by the mother plant.

The anatomy of *Acacia mollissima*, with special reference to the distribution of tannin, P. A. VAN DER BYL (*Union So. Africa Dept. Agr. Sci. Bul.* 3 (1914), pp. 32, figs. 41).—The author describes the anatomy of *A. mollissima*,

or black wattle, with reference to the location of tannin. This is said to be present in every organ of the plant, but mostly in the phloem region of trees from six to ten years old, young branches and leaves having too low a tannin content to be profitably used.

Biochemical investigations of saponins, MARIE KORSKOFF (*Rev. Gén. Bot.*, 26 (1914), No. 306, pp. 225-244).—The author studied the occurrence, distribution, and rôle of saponin in *Saponaria officinalis* and *Agrostemma githago*.

No saponin was found in the leaves or pericarp, and none in the very young seed in sufficient quantity to be detected. It appears, however, in the seed as it reaches maturity. This has led to the conclusion that saponin is either formed in minute quantities in the leaves, from whence it passes to the stems from the sugars, or it is formed in the stems themselves. The author considers that within the seed saponin is formed at the same time as the other reserve materials. The fact that in the process of germination the saponin does not diminish leads him to believe that it is not utilized as a food reserve.

On a chemical peculiarity of the dimorphic anthers of *Lagerstroemia indica*, with a suggestion as to its ecological significance, J. A. HARRIS (*Ann. Bot. [London]*, 28 (1914), No. 111, pp. 499-507, figs. 2).—The author states that in *L. indica* the stamens are dimorphic, those of the outer whorl being larger than those of the more central yellow group, and differing from them also in both color and contained pollen. It is claimed that the differentiation observable is physiological as well as morphological, the underlying cause of the phenomena appearing to be chemical rather than physical. The morphological and physiological dimorphism is considered to be a case of specialization of parts to facilitate pollination.

Studies on the floral biology and pathology of the olive, L. PETRI (*Studi sulle Malattie dell' Olivo*, V. Rome: R. Staz. Patol. Veg., 1914, pp. 5-64, figs. 5).—The author concludes from studies detailed that a constant and considerable arrest of an ovarial development more or less precocious may be noted in both cultivated and wild olive plants under good or deficient conditions of growth, and that among the external factors which may condition almost complete sterility is prolonged drought. Defoliation produces the same effect, as may any cause of deficient water transfer within the plant, and to this may be added abortion of the anthers.

It is stated that in a given plant, and even within the same floral shoots of the more fertile individuals, some flowers may show an arrest of ovarial development at various stages, the percentage of ovarial abortions showing periodic oscillations bearing some relation to vegetative conditions. The arrest of development in the ovaries is held to have one cause in a deficiency of nitrogenous material, this deficiency seeming to be related to insufficient absorption of nitrates, as well as to diminution, more or less lasting, of the activity of the processes of synthesis of nitrogenous substance. Vegetative multiplication is the means, but not the cause, of perpetuation of this pathological deviation, and it is considered advisable to reject for grafting purposes all plants showing high percentages of ovarial abortion.

In the present state of knowledge the constancy of ovarial abortion in olives may be regarded, it is thought, as the consequence of a modification, difficultly reversible, of some physiological property of floral shoots, under the influence, more or less prolonged, of exceptional nutritional conditions, by direct or indirect action of the external medium in relation to profound modifications of the property of absorption and transfer by the roots.

Mutation en masse, H. H. BARTLETT (*Amer. Nat.*, 49 (1915), No. 579, pp. 129-139, figs. 9).—It is stated that during the author's experiments with *Oenothera* two species have been discovered, some strains of which give rise by mutation

to dwarfs occurring in both cases in unexpectedly large numbers. The less complicated of these two cases (*Æ. reynoldsii* n. sp.), with some of its descendants, is discussed as regards some studies made thereon.

The phenomenon presented by *Æ. reynoldsii*, called here mutation en masse, appears in one of the short-styled self-pollinating species. It seems clear to the author that mutation en masse bears a certain degree of resemblance to Mendelian segregation. No explanation suggests itself for the enormous surplus of dwarfs in the progenies exhibiting diversity, unless perhaps it is that the results are complicated by selective germination or selective mortality. At any rate the ratios thus far obtained do not conform to any Mendelian expectation. The origin of mutant *bilonga* from mutant *debilis*, it is thought, may instance the origin of a new character.

Studies in pea varieties and hybrids therefrom, H. KAPPERT (*Ztschr. Induktive Abstam. u. Vererbungslehre*, 13 (1914), No. 1-2, pp. 1-57, figs. 20).—This is a study, in some detail, of the several characteristics as regards the starch grains, surfaces, chemical constituents, physical peculiarities, etc., of some garden varieties of peas and their hybrids.

A flora of Cuba, M. G. DE LA MAZA and J. T. ROIG (*Estac. Expt. Agron. Cuba Bol.* 22 (1914), pp. 182, pls. 33, fig. 1).—This work is in four parts. The first deals in a general way with living plants (listing genera) and fossils (listing families, genera, species, etc.) of this region. The second gives a discussion of the flora of Cuba in relation to that of other regions. The third indicates collections and other facilities for botanical study. The fourth deals with plants in their economic aspects.

Geography and vegetation of Northern Florida, R. M. HARPER (*Fla. Geol. Survey Ann. Rpt.*, 6 (1914), pp. 163-437, figs. 51).—The author gives the results of several years' study on the original distribution of the native vegetation in relation to the several geographical divisions of the State of Florida, as contributing to a better understanding of the complex relations existing between native vegetation, topography, drainage conditions, and soils.

Lists of native plants and an index of plant names are included.

Plant ecology and floristics of Salton Sink, S. B. PARISH (*Carnegie Inst. Washington Pub.* 193 (1914), pp. 85-114).—This contribution includes a citation of the very scanty existing botanical literature on the Salton Sink; a discussion of the derivation, distribution, and determining factors of the flora; a description of the various floral formations and associations; a consideration separately of the trees as classed with regard to soil moisture; a numerical analysis of the flora; and a catalogue of the plants collected in this depression.

Movements of vegetation due to submersion and desiccation of land areas in the Salton Sink, D. T. MACDOUGAL (*Carnegie Inst. Washington Pub.* 193 (1914), pp. 115-182, pls. 18, figs. 2).—An account is given in considerable detail of studies carried on at intervals since 1904 in the Salton Sink, as concerned mainly with organisms overwhelmed by floods, with the physical changes which follow emersion, and with the biological mechanism of reoccupation in areas emerging from the water as related to the present distribution of plants and animals. Such factors are considered in this connection as soil, climate, precipitation, and changes occurring in solutions and in precipitates. Submergence and emergence with corresponding biological alterations are thought to have occurred here many times in the last few centuries, and the accompanying complex interplay of biological and mechanical agencies is partly described and partly suggested.

The behavior of certain micro-organisms in brine, G. J. PEIRCE (*Carnegie Inst. Washington Pub.* 193 (1914), pp. 49-69, pls. 3, fig. 1).—Reporting a further study (*E. S. R.*, 30, p. 431) of organisms in the Bay of San Francisco, some of

which endure great and rapid changes of concentration in the saline solutions, the author shows that several of these present remarkable illustrations of adaptability and plasticity. Changes in temperature exercise no very evident influence on the behavior of the brine organisms, but changes in concentration of the brine are reflected in the behavior of the brine algæ, also in marked effects as regards cell permanence or cell division.

The red color of concentrated brines in the salterns and of the salt piled for drainage is due to a chromogenic bacillus, inoculation with which turns salt codfish red.

The osmotic, adsorptive, and other relations noted are considered to justify further study on account of their more general bearings.

FIELD CROPS.

Root systems of agricultural plants, J. G. MASCHHAUPT (*Verslag. Landbouwk. Onderzoek. Rijkslandbouwproefstat.* [Netherlands], No. 16 (1915), pp. 76-89, pls. 5).—This describes a method of removing a shaft of soil of sufficient breadth and depth to include the root systems of the plants under investigation. After cutting away the soil from one side of the proposed shaft, a board studded with needles of sufficient length to penetrate the shaft's breadth (25 cm.), in order to secure the roots in approximately their original positions, is pressed or driven in a vertical position against the shaft, which the needles penetrate. The shaft is then cut loose on the opposite side by driving down a piece of sheet iron to the desired depth, and the soil is carefully washed away from the roots.

The influence of phosphatic fertilizers on root development, R. D. WATT (*Rpt. Austral. Assoc. Adv. Sci.*, 14 (1913), pp. 661-665, fig. 1).—This paper records data taken from water-culture, pot-culture, and field experiments that show an increased root development of barley and wheat apparently due to the application of phosphatic fertilizers. The depths to which roots of wheat penetrated on unmanured plats ranged from 13 to 37 in. and on fertilized plats from 27 to 38 in.

The geographical distribution of the field crops of India, T. H. ENGELBRECHT (*Abhandl. Hamburg. Kolon. Inst.* 19 (1914), Ser. E, pp. IX+271; *Atlas*, pls. 23).—Part 1 of this article treats of the distribution of about 70 of the field crops of India. Part 2 consists of maps showing the distribution of the principal field crops.

[**Studies with field crops in Montana**] (*Montana Sta. Rpt.* 1914, pp. 391-393, 397, 398).—Among other work of the year, it is mentioned that mangels, Gehu and Dakota white flint corn, and Pilot navy beans were grown with success, but that sorghum, Kafir corn, cowpeas, soy beans, and grasses were unsatisfactory. Seeds of alfalfa and several clovers treated with sulphuric acid before planting gave lower yields of hay than check plats. Contradictory results are reported regarding thinning and spacing potatoes, while mulching did not give so good results as cultivation. Favorable results are reported in improving potatoes by hill selection.

Grasses and forage crops (*Mass. Bd. Agr. Bul.* 3 (1915), 2 ed., rev., pp. 126, pls. 5, figs. 3).—This is a revised second edition of the bulletin already noted (*E. S. R.*, 23, p. 530) with additional papers on Green Crops for Summer Soiling, by J. B. Lindsey (*E. S. R.*, 23, p. 580); How to Supplement a Short Hay Crop, by C. S. Phelps; New England Pastures, by J. S. Cotton; and Alfalfa for New England, by A. D. Cromwell.

Experiments on permanent grass land, 1915 (*Agr. Students' Gaz.*, n. ser., 17 (1915), No. 4, pp. 162-165).—This article notes results of manurial experiments at Cirencester, England, that have been in progress over 20 years.

"Generally the ammonium sulphate gave rather better returns than the corresponding plats with sodium nitrate. Sodium nitrate alone has evil effects on the grass, but ammonium sulphate alone is not so injurious here. The residues of previous manuring for 20 years with rape cake, discontinued after 1911, gave an increase of 6 cwt. of hay. The increase on the basic slag plats was 6 to 7 cwt., rather more this year than on the superphosphate alone plat, where it was 5½ cwt., but the weight of slag given is double that of the superphosphate. The hay from the plat with superphosphate and residues of potash salts was exceedingly rich in Leguminosæ."

[Fertilizer experiments] (*County Northumb. Ed. Com. Guide to Expts. 1915, pp. 10-87, figs. 2*).—This gives some results of manurial treatments of pastures and meadows and rotation experiments.

Pasture grasses: Their cultivation and management, E. BREAKWELL (*Dept. Agr. N. S. Wales, Farmers' Bul. 96 (1915), pp. 105, pl. 1, figs. 57*).—The author discusses the treatment of native pastures, including overstocking, deterioration, and burning off, and cultivated pastures; classifies useful grasses according to soil, height of grass, and habits of growth; and describes many useful grasses, both introduced and the best native grasses of New South Wales.

Ecology of the purple heath grass (*Molinia cærulea*), T. A. JEFFERIES (*Jour. Ecology, 3 (1915), No. 2, pp. 93-109, pls. 2, figs. 2*).—This article gives the results of an ecological study of *M. cærulea* on 3 square miles of moors 6 miles from Huddersfield, England. The morphology and biology of *Molinia*, factors in its distribution (soil content and acidity), and the invasion and retrogression of *Molinia* are discussed.

A new species of forest grass (*Spodipogon lacei*), R. S. HOLE (*Indian Forest Rec., 5 (1915), No. 6, pp. 6, pls. 4*).—This describes a grass closely allied to *S. sagittifolius* and given the name of *S. lacei*.

Variety tests with millet and sunflowers, P. R. FEDOROV (*Bezenchuk. Selsk. Khoz. Opytn. Stantsiia, No. 60 (1914), pp. 6*).—Variety tests with millet showed yields ranging up to 2,133 lbs. per acre when the soil was plowed to a depth of 7 in.

Tests with sunflowers showed "Green" to be the heaviest yielder of seed (720 lbs. per acre). It is noted that this variety was entirely free from dodder, which for two seasons greatly infested the other varieties.

The effect of the association of legumes and nonlegumes, W. B. ELLETT, H. H. HILL and W. G. HARRIS (*Virginia Sta. Tech. Bul. 1 (1915), pp. 28-36, figs. 3*).—The experiments outlined in this bulletin were conducted in order to account for the high percentage of protein found in samples of Kentucky blue grass grown in Virginia. They consisted of the production (beginning in 1911) of Kentucky blue grass, timothy, and corn grown separately and in association with white clover, red clover, and beans, respectively, in concrete tanks made in the greenhouse for the purpose, and supplemented by field tests.

The data obtained by harvesting and analyzing the crops showed with blue grass and white clover no direct benefit from the association. With timothy and red clover no increase in protein was shown the first year, but in 1913 and 1914, however, some benefit was found. When corn and beans were grown in the greenhouse the corn was benefited by the association.

The high protein content of the grasses was chiefly accounted for by the early age at which they were analyzed. The protein content of the blue grass sown January 1, 1911, and cut March 1, April 1, May 1, June 1, December 1, 1911, and February 4, 1912, is reported for the respective dates as 32.71, 24.37, 25.27, 18.2, 19.93, and 16.91 per cent (dry matter basis). The protein content of timothy sown January 1, 1911, and cut March 1, April 1, May 1, and June 1, 1911, is reported as 30.27, 24.35, 24.68, and 18.59 per cent.

Vegetative regeneration of alfalfa, O. T. WILSON (*Science, n. ser.*, 42 (1915), No. 1073, pp. 126, 127).—This article reports the vegetative growth of cuttings from alfalfa plants when these cuttings were left on the moist soil of experimental pots in the greenhouse. "After a week it was found that fragments of several descriptions [portions of stems, portions of petioles, petioles with blades attached, leaflets without petioles attached, and portions of the leaf blade] had rooted firmly and were developing into healthy shoots."

Experiments with corn in 1914, V. SVISHCHEV and B. AKSENOV (*Bezenchuk. Selsk. Khoz. Opytn. Stantsiâ, No. 61 (1914), pp. 6*).—This records variety tests with maize and shows that in general the local varieties produced greater quantities of dry matter per acre than the imported American varieties. The use of manure was found to be unprofitable. In general the use of listers gave better yields than did corn planters.

Soil moisture and tillage for corn, J. G. MOSIER and A. F. GUSTAFSON (*Illinois Sta. Bul. 181 (1915), pp. 563-586, figs. 7*).—This bulletin contains data compiled from results of experiments conducted in Illinois and in several other States in cultivating the corn crop on various kinds of soil. These data have been so edited as to develop principles that should be observed in order to secure the best results in the production of corn, and are summarized as follows:

"A deep, well-prepared seed bed is essential for aeration, proper root development, and conservation of moisture. It gave a gain of 14.5 bu. (\$7.25 at 50 cts.) per acre over no seed bed. Killing weeds is the most important factor in cultivating corn on brown silt loam. No weeds gave an increase over weeds of 38.6 bu. of corn, a gain of \$19.30 per acre. Weeds reduce the yield of corn more by robbing it of plant food and light than by depriving it of moisture. Irrigation on a weed plat gave an increase of only 3.8 bu. As an average of 16 tests in eight years, killing weeds without cultivation produced a gain of 17.1 per cent. or 6.7 bu. per acre, over ordinary cultivation. Three-fourths of the corn roots are in the plowed soil, and as plants develop no unnecessary roots, any injury to them results in a lower yield. Four-inch pruning six inches from the hill reduced the yield 16.9 bu. The cultivated soil, especially in periods of drought, is too loose and dry for proper root development; consequently the plant is deprived of the food which it contains. After the roots are well distributed through the soil little moisture can escape, even from uncultivated land.

"On gray silt loam on tight clay in southern Illinois, as a three-year average, preparation of seed bed gave an increase of 21.5 bu.; killing weeds by scraping with a hoe gave a gain of 21 bu. over allowing them to grow; and fertilization gave an increase of 14.2 bu. Ordinary shallow cultivation gave a yield of 31.2 bu. per acre, while killing weeds without stirring the surface gave 31.5 bu.

"The proper type of cultivation is deep enough to kill the weeds but shallow enough to reduce root injury to the minimum. On Illinois soils a good seed bed, killing weeds, and soil enrichment are the important factors in growing corn. Cultivation is beneficial for aeration of heavy soils, clays, and clay loams. Cultivation raises soil temperature early in the season and lowers it later. Subsoiling on gray silt loam on tight clay at Odin caused a decrease of 2.7 bu. per acre.

"Results of deep-tilling tests so far conducted by this station do not warrant recommending the purchase and use of deep-tilling machines in this State."

Tests of varieties of corn, W. E. HANGER (*Maryland Sta. Bul. 190 (1915), pp. 181-202, pls. 9*).—This bulletin gives results of tests of varieties of corn grown at the station and by farmers in different sections of the State.

During the years 1903 to 1914, inclusive, the yields at the station ranged from 31.68 to 86.18 bu. of grain per acre. The highest average yield, 70.36 bu.

per acre, for the five years 1903 to 1907, inclusive, was made by St. Omer. The highest average yield of the seven years 1908 to 1914, inclusive, was made by U. S. P. B. No. 120, namely, 59.39 bu. per acre, followed closely by St. Omer with 59.31 bu.

Twenty-two varieties of corn are described.

Variety tests of corn for 1914, G. M. GARREN (*North Carolina Sta. Bul. 230 (1915), pp. 3-12*).—This bulletin gives data on over 20 varieties of corn grown in 1914 at the station and at the Buncombe, Iredell, and Edgecombe test farms and summaries for a few varieties covering a period of six years (1909-1914) at the Iredell and Edgecombe test farms. The tables include data on stand, height, number of ears, yield, and shelling capacity. Among the higher yielding varieties were First Generation Cross No. 182 of the Bureau of Plant Industry of the U. S. Department of Agriculture, Biggs Seven-Ear, and Weekleys Improved.

Report on variety tests of cotton for 1914, R. Y. WINTERS (*North Carolina Sta. Bul. 231 (1915), pp. 3-18*).—The data in this bulletin show the yield of seed cotton per acre, yield of lint and of seed, percentage of lint, length of staple, weight of 100 bolls, and stand for the several varieties. The results obtained from seed secured from both within and out of the State are summarized as follows:

At the experiment station farm the 65 varieties of short-staple cotton tested ranged in yield between 1,375 and 765 lbs. of seed cotton per acre, with an average of 1,023 lbs. The 15 varieties secured within the State ranged between 1,160 and 860 lbs., with an average of 974 lbs., indicating the need of more careful selecting of seed in the State. The 12 long-staple varieties ranged between 1,160 and 875 lbs., with an average of 1,009 lbs.

At the Edgecombe farm the 16 short-staple varieties tested ranged in yield between 1,305 and 870 lbs. of seed cotton per acre, with an average of 1,154 lbs. The 10 short-staple varieties from points within the State ranged between 1,310 and 870 lbs., with an average of 1,113 lbs. The 6 varieties from points out of the State ranged between 1,305 and 1,140 lbs., with an average of 1,222 lbs. The long-staple cottons ranged in yield between 1,520 and 1,045 lbs., with an average of 1,283 lbs.

The variety test at the Iredell farm contained 25 short-staple varieties and 8 long-staple varieties, of which 9 short and 2 long staple varieties came from points in the State. The short-staple varieties from out of the State gave an average yield of 618.4 lbs. of seed cotton and 246 lbs. of lint per acre as compared with 738 lbs. of seed cotton and 288 lbs. of lint for the locally grown varieties. The 4 leading varieties were from seed secured in the State. Four of the 9 local varieties produced lint less than seven-eighths of an inch in length.

Cauto tree cotton, H. H. COUSINS (*Bul. Dept. Agr. Jamaica, n. ser., 2 (1915), No. 8, pp. 334, 335, pls. 3*).—This notes the successful cultivation of a wild variety of cotton, *Gossypium brasiliense*, var. *apospermum*, discovered in the jungles of Cuba. Yields of this perennial cotton reached 600, 700, and 900 lbs. of seed cotton per acre in successive years. The lint as grown in Jamaica is stated to be of good quality.

A preliminary note on the factors controlling the ginning per cent of Indian cottons, H. M. LEAKE (*Jour. Genetics, 4 (1914) No. 1, pp. 41-47*).—This presents the results of a study to determine factors that influence the ginning percentage of cotton and make it clear how the offspring of two parents, each having a ginning percentage of from 25 to 26, could have a percentage ranging from 18 to 36.

It was discovered that the ginning percentage was not directly measured by any single one of the characters of volume of seed, specific gravity of seed, number of fibers arising from a single seed, or the weight of the individual fibers. By using the coefficients of correlation between the characters of number of fibers per seed, weight of 1,000 fibers, and volume of seed, it was found that one, the number of fibers per seed, had a marked effect on the value of the ginning percentage.

Fiber industry of British East Africa, A. WIGGLESWORTH (*London: John Bale, Sons & Danielsson, Ltd., 1915, pp. 15, fig. 1*).—A paper read at the Third International Congress of Tropical Agriculture, held at London in June, 1914, and giving an account of the methods of production and manufacture of fiber from *Sansevieria* and sisal.

The growth and preparation of Italian hemp, A. WIGGLESWORTH (*London: [Author], 1914, pp. 39, figs. 18*).—This gives methods employed in Italy in the production of hemp and the manufacture of the fiber.

Investigations on hops.—V. On the aroma of hops, J. SCHMIDT (*Compt. Rend. Lab. Carlsberg, 11 (1915), No. 3, pp. 149-163*).—This describes experiments in growing and breeding hops in connection with work previously noted (*E. S. R.*, 31 p. 526). The results have been summarized as follows:

“In exact investigations as to hops, whether of botanical or chemical, practical or scientific nature, the work should be based upon clones, as otherwise the results may be liable to justifiable criticism.

“Among the hop plants cultivated in the experimental garden of the Carlsberg Laboratory, there were in 1911 two American plants (labeled Oregon Cluster and New York Spaulding English Cluster), the hops of which exhibited a very peculiar turpentine-like aroma, so widely different from that of all European varieties that a single hop could at once be recognized by the smell among hundreds of others. Cultivation experiments made during the years 1911, 1912, 1913, and 1914 showed that this aroma remained apparently constant in our climate in these two plants and their clones.

“Crossing experiments made in 1912, 1913, and 1914 with the two American plants and Danish males showed that the turpentine-like aroma was transmitted to between one-half and three-fourths of the offspring plants, without regard to whether the hops themselves retained the appearance peculiar to those of the mother plant.

“From the experiments already mentioned, as well as from several others made with European varieties (e. g., those from Saaz in Bohemia) it would seem that the aroma of hops is not to be regarded as so volatile a character, or so entirely due to purely local conditions, as has generally been believed.”

Investigations on hops.—VI. On the amount of lupulin in plants raised by crossing, J. SCHMIDT (*Compt. Rend. Lab. Carlsberg, 11 (1915), No. 4, pp. 165-183*).—In experiments in breeding hops to increase the lupulin content, 21 females of Danish, English, German, and Austrian origin, all cultivated plants, were crossed with wild Danish males in 1911. The lupulin (total content of hard and soft resins) contents of the seedling offspring ranged from 7.3 to 19.7 per cent as maximums of the several groups of different parentage. The average lupulin content of the offspring of any given parentage showed lower than that of the mother plant, but there were a few individuals that showed a higher content. This was true in spite of the fact that wild males, “presumably genotypically poor in lupulin,” were used.

Thus by vegetative propagation the author sees a method of improvement by using the highest plus variant among the offspring.

Investigations on hops.—VIII. On the flowering time of plants raised by crossing, J. SCHMIDT (*Compt. Rend. Lab. Carlsberg, 11 (1915), No. 4, pp. 188-*

198).—This article notes the earliness and lateness in time of flowering of crosses between cultivated English and Austrian female hops and wild Danish hops. The dates of flowering of the offspring showed a wide variation, the number of individuals decreasing greatly from the average toward the two extremes and thus offering an opportunity for improvement by selection and vegetative propagation.

"A comparison of offspring and mother plants reveals the fact that the mean flowering date of the former is often essentially different from that of the latter. This made itself apparent in our experiments as a retardation of the flowering time in the offspring of early plants, and an advancement of the same in those of later varieties, while in the offspring of intermediate mother plants, little or no difference was observed."

Report on collective experiments: Results of introducing in 1913 fertilizers on lupines, S. P. KULZHINSKIĪ (*Abs. in Zhur. Opytn. Agron. (Russ. Jour. Expt. Landw.)*, 15 (1914), No. 3, pp. 268, 269).—Fertilizer experiments with blue lupines, reported from 42 fields, show that the use of 2 poods (72 lbs.) of K_2O as potash salt per dessyatina (2.7 acres) gave increases in yields ranging from 105 to 631 poods per dessyatina in 25 cases. Ten cases reported decreased yields with potash. The use of 2 poods of P_2O_5 per dessyatina as superphosphate showed increases in yields ranging from 31 to 710 poods in 15 fields, and decreases in 19 cases ranging from 17 to 1,212 poods. The average of all the P_2O_5 tests showed decrease in yield of 72 poods. With the combined application of 2 poods of K_2O and 2 poods of P_2O_5 per dessyatina, 18 cases reported increases up to 626 poods, while 16 reported decreases in yields of green forage up to 1,264 poods, with an average decrease of 34 poods of green forage by the use of the combination.

The use of seed potatoes from light soils on richer and heavier soils, SCHNEIDEWIND (*Landw. Wehnschr. Sachsen*, 17 (1915), No. 3, pp. 18, 19; *abs. in Internat. Inst. Agr. [Rome]*, *Mo. Bul. Agr. Intel. and Plant Diseases*, 6 (1915), No. 4, pp. 575, 576).—This notes the increase in yield, ranging from 2,000 to 7,100 lbs. per acre, of potatoes returned to a loess-loam soil after having been planted a season or two on a sandy soil.

Pictorial practical potato growing, W. P. WRIGHT and E. J. CASTLE (*London and New York: Cassell & Company, Ltd.*, 1913, pp. 152, figs. 50).—This book treats of intensive methods of production and of insect pests and fungus diseases of potatoes, with notes on the cooking of potatoes.

The prototype of the cultivated sorghums, C. V. PIPER (*Jour. Amer. Soc. Agron.*, 7 (1915), No. 3, pp. 109-117).—In this article the author reviews the studies of earlier investigators and discusses various forms and subspecies of *Andropogon sorghum* of African origin as possible prototypes. He concludes that "there is yet too much to be learned about the wild sorghums to determine with any assurance which are the actual prototypes of the cultivated sorghums. It seems perfectly clear, however, that *A. halepensis* and its subspecies as above defined are not at all concerned. It appears equally clear that not all of the wild races of *A. sorghum* can be considered as probable ancestors of the cultivated varieties. The ones most likely to belong in this category are *A. hewisoni*, *niloticus*, *drummondii*, and possibly *effusus* and *verticilliflorus*. The last two races as at present understood are very variable and perhaps each name stands for several distinct plants. The problem of the wild ancestors of the cultivated sorghums is now so narrowed that it is reasonable to hope that the details may in the near future be definitely determined."

Variations in soy bean inoculation, J. H. VOORHEES (*Jour. Amer. Soc. Agron.*, 7 (1915), No. 3, pp. 139, 140).—This notes the absence of nodules on the roots of certain varieties of soy beans although the seed had been inoculated

and grown in mixture with other varieties that formed nodules abundantly on their roots.

The cultivation of sugar beet in Norfolk and Suffolk, C. S. ORWIN and J. ORR (*Jour. Bd. Agr. [London], 21 (1915), No. 11, pp. 969-987*).—This article discusses methods and the economics of growing sugar beets in Norfolk and Suffolk counties, England, and gives statistical data for the years 1912, 1913, and 1914, showing the itemized cost of production on 16 farms that had from 4 to 70 acres of sugar beets. In Norfolk the cost per acre ranged from £7 5s. 6d. to £12 4s. 10d., and in Suffolk from £7 9s. 7d. to £12 11s. 6d. The yields in Norfolk ranged from 8 tons to 13 tons 5 cwt., and in Suffolk from 2 tons 7½ cwt. to 9 tons 6 cwt. per acre.

Single-germ beet seed, C. O. TOWNSEND (*Jour. Heredity, 6 (1915), No. 8, pp. 351-354, fig. 1*).—This article notes the success attained in the production of single-germ seeds in sugar beets by selection. The author states that "our selected plants are now producing about 75 per cent of single-germ seeds, and individual plants in a few cases show a somewhat higher percentage than this. The work and progress of single-germ beet seed production is based upon the fact that certain beet plants possess the ability so to develop the seed stems that the buds and flowers are separated from each other in the process of growth. This tendency to separate the flowers and thereby to produce single-germ seeds seems to be transmissible from parent to offspring; whether or not this will become a fixed character time only can tell. The indications are that this character will become fixed."

Report of the seedling expert. H. B. COWGILL (*Rpt. Bd. Comrs. Agr. P. R., 3 (1913-14), pp. 55-63*).—This reports work in progress in sugar-cane culture.

In fertilizer experiments with second ratoon cane it was shown that the best yield (15.65 tons per acre) was obtained by the use of 120 lbs. each of nitrogen and potash and 60 lbs. of phosphoric acid. This yield was 9.35 tons above the average of the check plats. The application of 2,000 lbs. of lime per acre increased the yield about one-third over an average of all fertilized plats.

In spacing experiments 1½ continuous rows of seed and seed placed end to end gave larger yields than one seed every 2 ft., 1 seed every 3 ft., 2 seeds every 3 ft., and 2 seeds every 4 ft. in rows 4, 5, and 6 ft. apart.

Results of variety tests of cane grown on lowlands and highlands are given.

Manurial experiments, H. A. TEMPANY ET AL. (*Imp. Dept. Agr. West Indies, Sugar-Cane Expts. Leeward Isl., 1913-14, pt. 2, pp. 52-78, pls. 2*).—This article gives in detail the results of manurial experiments with sugar cane for the season 1913-14 and a summary including results for several years.

"It has been shown that under average conditions the amounts of manurial constituents supplied in a dressing of pen manure at the rate of 20 tons to the acre, applied before the crop of plant cane is established, provide sufficient food for the production of a crop of plant canes, first ratoons, and possibly second ratoons; the augmentation of this supply by an additional dressing of pen manure or artificial manures is unattended by corresponding substantial increases. This result is attributed to the limitation of the water supply available for growth.

"With an increase in potential productivity consequent on a more regular water supply it seems reasonable to suppose that such additional manuring would be likely to prove profitable. The beneficial action of quick-acting nitrogenous manures on ratoon canes is attributed to the fact that they stimulate recovery from the check to the growth incident on the reaping of the previous crop, whereby the plant is enabled rapidly to resume its physiological functions, and to continue to utilize the store of manurial material derived from the original application of pen manure. Additional confirmation is given to

this view by the results obtained when quick-acting nitrogenous manures are applied in two doses instead of one. A decrease of yield is seen invariably as a result of the division of the application, the inference being that by the time the late dose is given the canes have already made such growth as to preclude the extra supply of readily available nitrogen exercising any great effect. . . .

"Additional investigations have further demonstrated that appreciable residual action is felt on succeeding crops of cane as the result of the applications of artificial manures to any one crop, the effect being seen in first ratoons when the applications are made to plant canes, and in the second ratoons when they are made to first ratoons. In estimating the effect of a manurial dressing, therefore, it is necessary to allow for the existence of possible residual action. In relation to the recently introduced nitrogenous manures, nitrolim and nitrate of lime, it has been shown that nitrolim is ineffective as a manure when applied to ratoon canes, but nitrate of lime possesses a value nearly equal to that of sulphate of ammonia. Applications of molasses to ratoon canes have proved to be unproductive of benefit; the effect of similar applications to plant canes is under investigation. The effect of small dressings of lime has been negative, but when larger dressings of marl have been given benefit has been derived, especially in the case of heavy noncalcareous soils. The effect of intertillage on ratoon canes has been found to be a beneficial one."

Catalytic or fecundating stimuli and mutation in *Nicotiana*, A. SPLENDORE (*Bol. Tec. Cultiv. Tabacchi [Scafati]*, 14 (1915), No. 1-2, pp. 3-37, pls. 27).—This describes offspring derived from 26 crosses between varieties of *Nicotiana* with each other and with several species of Solanaceæ and Scrophulariaceæ as female parents.

The Georgia velvet bean, J. BELLING (*Jour. Heredity*, 6 (1915), No. 7, p. 290).—This article notes an early variety of velvet bean now grown in Georgia, the first flowers of which appear nearly two months earlier than those of the Florida velvet bean. The author concludes that "from crosses between the Yokohama and the Florida the Florida has a factor for late flowering, *H*, which the Yokohama does not possess. Hence it may be supposed that the Georgia velvet arose from the Florida velvet by the "spontaneous" loss of the factor *H*. Since *H* is dominant, the early plants would appear only in the second generation."

Variation in pure lines of winter wheat, C. G. WILLIAMS (*Proc. Soc. Prom. Agr. Sci.*, 35 (1914), pp. 89-94).—This article gives the results of a series of experiments begun at the Ohio Experiment Station in 1907 and 1908 to study the variation with respect to heritability of length of head, size of kernel, and protein content of pure line selections of wheat. From continued selections for several generations no heritable variation of any of these characters could be detected. The data show that the seed of either extreme character has a tendency to produce a crop having the general average.

Determination of seeds of *Cuscuta trifolii* and *C. suaveolens* by anatomical methods, J. BERNÁTSKY (*Kísérlet. Közlem.*, 18 (1915), No. 2, pp. 207-222, figs. 7).—This gives results of a microscopical study of the structure of the seeds of *C. trifolii* and *C. suaveolens*, which may ordinarily be distinguished by their size.

When, as frequently happened, the seeds of *C. suaveolens* were unusually small and those of *C. trifolii* were unusually large, the observation of distinguishing characteristics other than size became necessary. The following characteristics were noted, respectively: Length of cells of the first layer of palisade cells, 11 to 19 μ and 18 to 28 μ ; length of cells of the second layer of palisade cells, 16 to 24 μ and 40 to 52 μ ; length of the first of layer palisade cells near the hilum from 12 to 19 μ and 18 to 40 μ ; length of the second layer, 32 μ and 56 to

90 μ . The starch grains in the endosperm of the small seeds of *C. suaveolens* were massed together and measured about 7 μ ; those of the large seeds of *C. trifolii* were single and measured about 4 μ .

The weed *Galinsoga parviflora*, K. MÜLLER (*Arb. Deut. Landw. Gesell.*, No. 272 (1914), pp. 31, pls. 6).—This article treats of the characteristics of this weed, and discusses its development, vegetative requirements, and methods of seed distribution. Methods of eradication are described, and its usefulness as well as its undesirable qualities and legislative regulations for its control in Germany are noted.

Methods of determining weight per bushel. H. H. LOVE (*Jour. Amer. Soc. Agron.*, 7 (1915), No. 3, pp. 121-123, pl. 1).—This describes an apparatus designed by H. W. Teeter, and presents data showing that by its use it is possible to make comparable all weight per bushel results.

A method for testing the breaking strength of straw. B. C. HELMICK (*Jour. Amer. Soc. Agron.*, 7 (1915), No. 3, pp. 118-120, pl. 1, fig. 1).—This describes an apparatus for determining the breaking strength of straw and gives some data showing its satisfactory use.

HORTICULTURE.

[Report of horticultural investigations] (*Montana Sta. Rpt.* 1914, pp. 395-397).—Measurements of fruit trees on the cultural test plats at the horticultural substation in the Bitter Root Valley show that those on the plat cropped with potatoes have made the best growth since planting in 1908. Those on the clover plat where the crop has been cut and left on the ground rank next in growth, and those on the clean cultivated plats rank third. The trees on the cultivated plat are now beginning to show rosette, indicating that while the young trees may thrive for a time under clean cultivation bearing trees can not be expected to continue in good condition under such a system of culture.

Of the apple varieties being tested at this substation the Newtown Pippin and the Spitzenburg have been eliminated as maturing too late. The varieties of apples which have been so seriously affected by blight as to render them of doubtful value for commercial planting are Opalescent, Jonathan, Winter Banana, Wismer Desert, Wagener, and Wealthy. Practically all bearing pear trees were killed by blight during the summer of 1914. The varieties represented were Bartlett, Seckel, Clapp, and Flemish Beauty.

A test of mulching as compared with cultivation in growing vegetables without irrigation has been carried on at the home station. The following vegetables were grown under cultivation and under straw mulch: Beets, cabbage, carrots, cauliflower, cucumbers, endive, kohlrabi, lettuce, onions, parsnips, peas, pumpkins, radishes, rutabagas, salsify, spinach, squash, sweet corn, Swiss chard, tomatoes, and turnips. With the exception of cabbage, in which the yield and the weight of heads, especially of the later varieties, were increased by mulching and of the late root crops in which the yield and quality were improved by mulching, cultivation seemed to give the best results. The straw mulch conserved more moisture than the cultivation but during warm weather reduced the soil temperature as much as 10° F. during the warmer part of the day. Under the climatic conditions at the station temperature seemed to be as important a factor as soil moisture in crop growth.

Some cultural experiments were conducted with celery. The seed started in greenhouses on February 14 produced an average of 30 per cent of seed stalks, while the same varieties started on March 14 produced a fraction over 1 per cent of seed stalks. Early plantings grown on very rich soil produced 38 per cent of seed stalks, while seed from the same stock planted in medium soil

produced only 18 per cent of seed stalks. Sandy soil gave 30 per cent of seed stalks in the case of early planting and but a slight percentage in the case of late planting. The results as a whole seem to indicate that early planting, soil overrich in organic matter, or soil too abundantly supplied with sand will encourage premature seeding.

A comparison of ridge and level cultivation in growing onions resulted in favor of the former method. Ridging apparently induced early maturity and the bulbs seemed to "bottom up" better.

Report of the horticulturist, C. F. KINMAN (*Porto Rico Sta. Rpt. 1914, pp. 17-22, pl. 1*).—A short progress report on investigations with fruits, vegetables, and miscellaneous plants (E. S. R., 31, p. 634).

Among the East Indian varieties of mangoes being tested Amini and Cambodiana were the most promising during 1914. Over 400 trees, including 60 imported varieties, were under cultivation. Work with yautias, dasheens, yams, sweet potatoes, etc., is being continued. Cooperative variety tests have been conducted near San Juan on the sandy coastal plains. The first crop of yautias grown on the sandy soils has been unsatisfactory, but few of the varieties proving sufficiently prolific to warrant commercial cultivation. Dasheens were more promising, though not heavy producers. Some varieties of sweet potatoes have given good returns, while many are not profitable under these conditions.

Some data are given on the cooperative fertilizer experiments with citrus fruits, the results of which have been published in full in a bulletin by the station (E. S. R., 33, p. 241). The cooperative experiments with coconuts have been extended to parts of the island where different weather conditions prevail. Eight harvests have been made since the fertilizer experiments were started in 1912. The trees under observation are old palms on sandy beach land suitable for coconut culture, but have been slow to respond to fertilizer treatment. In the last harvest, in plats given a complete fertilizer, the yield was in excess of that in check plats, although only small differences existed between the complete fertilizer and incomplete fertilizer and check plats. Data collected on individual coconut trees have shown a wide variation in yield, indicating the importance of seed-nut selection by those contemplating a new grove.

Experiments are being conducted to determine the advisability of growing leguminous cover crops in a young coconut grove. Jack beans (*Canavalia ensiformis*) and a few species of velvet beans (*Stizolobium* spp.) planted in April all made good growth and crowded out all native weeds and grasses. The *Stizolobium* spp. appeared to have a longer growing season and to produce a heavier crop of vegetation than the jack beans and are therefore preferable in coconut plantations. Leguminous cover-crop work was also conducted in citrus orchards and pineapple plantations. Much of the work was with the velvet bean species. These crops have made an excellent growth in both heavy and light soils where rainfall has been sufficient. They demand frequent cutting back, however, to keep them from injuring the trees. Notes are given on different species of velvet beans desirable for cover-crop planting. Both jack beans and pigeon peas were found to be injurious to the two varieties of pineapples under observation, Cabezona and Red Spanish, when planted in beds with them. The pigeon pea caused the most injury and the Cabezona pineapple was more severely injured than the Red Spanish.

A number of varieties of pineapples were planted more than two years ago in an area between 7-year-old *Pithecolobium saman* trees to test the effect of the shade and the nitrogen stored in the soil by the leguminous trees on the development of the pineapples. The shade trees were planted 20 by 20 feet

apart. The shade furnished by these trees was thin and the nodule growth on the roots very heavy, but the pineapples were almost a complete failure. They suffered most during the dry months. The conclusion reached as to growing pineapples with leguminous crops is that clean culture is necessary for the best development of the pineapples.

Report of the assistant horticulturist, T. B. McCLELLAND (*Porto Rico Sta. Rpt. 1914, pp. 23-26, pl. 1*).—A progress report on the station's work with coffee, cacao, vanilla, and some miscellaneous plants (E. S. R., 31, p. 637).

Some of the varieties of foreign coffee being tested came into bearing much later than Porto Rican coffee. Some produced a larger and others a smaller bean, and some are of excellent quality and others inferior. As to vigorous growth and amount of yield the Columnaris coffee, a sport from the ordinary Arabian type discovered in Java less than 30 years ago, is the most promising of the foreign coffees which have been tested on any scale and which have come into bearing up to the present time. The coffee fertilizer experiments do not show as yet that fertilizer can be applied with a financial gain. It seems quite probable that coffee should be included among the acid-tolerant plants, as benefits from lime alone applied to the acid soils at the station have been doubtful. Some of the handsomest coffee trees in the station plantings are in soil which is so acid as to require 1.0527 gm. of sodium hydroxid for neutralization of 1 kg. of soil. Considerable damage to coffee by rats is reported from various sections of the coffee district. From a young coffee tree with some limbs bearing variegated foliage and others normally green leaves seeds were planted to watch the inheritance of variegation. Of 30 seedlings from limbs with variegated foliage 17 had variegated cotyledonous leaves and two more were slightly off color, while of 36 seedlings from limbs bearing normally colored leaves none were variegated.

The yield of the 11-year-old cacao planting has shown an increase of nearly a third over that from the preceding year, and more than two and one-half times as great as the crop of three years ago. The most productive tree yielded the equivalent of about 4 lbs. of dried beans, worth 14 cts. a pound. The experiments with vanilla are being continued satisfactorily, some of the species being considered now worth cultivating as ornamentals in addition to their economic value.

Monthly tappings of rubber are being continued but the yields are so small as to discourage any planting. The cost of tapping and collecting alone has exceeded the value of the product. Among the economic plants obtained in Venezuela in 1913 are a black bean which has proved to be very vigorous and prolific and a delicious table corn, called "Cariaco" which has shown itself fairly well adapted to some local soils. Seedlings of mahogany, *Swietenia macrophylla*, have made exceedingly rapid and vigorous growth. Work with vegetables from seed brought from the North and grown in Porto Rico from one to many generations has been continued. Above everything else the marked effect of the planting season has stood out clearly. The existence of a tropical climate does not mean the ability to disregard the seasons.

[**Floral and vegetable trials at Wisley in 1914**], C. C. TITCHMARSH (*Jour. Roy. Hort. Soc., 40 (1915), No. 3, pp. 499-541, 544-548, 552-562, pls. 2*).—This comprises reports on variety tests of China asters, early flowering chrysanthemums, helianthus, heleniums, rudbeckias, French beans, and melons, tested under the direction of the Royal Horticultural Society in the Wisley gardens in 1914.

[**Miscellaneous floral and vegetable trials at Wisley, 1914**] (*Jour. Roy. Hort. Soc., 40 (1915), No. 3, pp. 549-551, 563-565*).—Notes similar to the above on a number of miscellaneous flowers and vegetables tested in Wisley in 1914.

Cabbage growing in California, S. S. ROGERS (*California Sta. Circ. 130 (1915)*, pp. 22, figs. 9).—A treatise on the culture of cabbage with special reference to California conditions. The following phases are discussed: Early history of cabbage growing, types and varieties, the cabbage as a truck crop, intercrop, and market garden crop, soils, moisture, climatic requirements, growing and subsequent care of the plants, time of planting and quality of seed, preparation of the field, planting and subsequent care of the plants, harvesting, storing, marketing, cost of production and profits, diseases, and insect pests.

The inheritance of size in tomatoes, F. E. PERRY (*Ohio Nat.*, 15 (1915), No. 6, pp. 473-497, figs. 5).—This paper reports a study of the inheritance of size in a red currant-yellow pear tomato cross which was made in 1911 and grown through four generations. The literature on character inheritance is briefly reviewed and a bibliography of literature dealing with inheritance is included.

Summarizing the results of the study as a whole the author finds that a more accurate representation of the size of the tomato fruits can be obtained from their weights than from linear dimensions. The size of fruit of the F_1 generation of the currant-pear cross is the geometrical mean between the parental sizes. From an examination of all available data upon the inheritance of fruit size in the F_1 generation it appears that when two varieties are crossed which differ widely in fruit size, as in the case of the currant and pear tomatoes, the F_1 fruit size will be nearer to the geometrical than the arithmetical mean, but when two parents similar in fruit size are crossed the size of fruits of the offspring will approach more nearly to the arithmetical than to the geometrical mean. The average fruit size of the F_2 generation does not exceed and is even slightly less than the average fruit size for the F_1 generation. Fruits of the F_2 and F_3 generations agree fairly well in respect to variability and average generation size. F_4 fruits show diminished variability and size.

Arboriculture, L. SAVASTANO (*Arboricoltura. Naples: Francesco Giannini & Sons, 1914*, pp. XI+848, figs. 268).—This work is essentially a treatise on the principles of fruit and nut growing, with special reference to kinds adapted to Italian conditions.

Part 1 reviews the history and development of arboriculture. Part 2 contains a census of cultivated and cultivable fruits and nuts and treats in detail of the biology of arboriculture, including also information relative to the acclimatization and geography of fruit trees. The succeeding parts treat in detail of the cultural technique, including propagation, grafting, pruning, manuring, tillage, irrigation, crossing, pollination, and artificial ripening; the establishment and management of orchards, groves, and plantations; and harvesting, packing, marketing, refrigeration, storage, transportation, insect pests, diseases and other enemies, orchard renovation, transplanting developed trees, windbreaks and hedges, and orchard valuation.

A bibliography of literature on the subject is also included.

A guide to the literature of pomology, E. A. BUNYARD (*Jour. Roy. Hort. Soc.*, 40 (1915), No. 3, pp. 414-449).—In this paper the author describes the more important pomological books of various countries and gives a list of important general pomologies; special monographs on various hardy fruits; general catalogues and reference works; treatises on grafting and budding, pruning and training, and culture under glass; and general works on fruit growing.

Small fruits for home and commercial planting, L. F. SUTTON (*West Virginia Sta. Bul. 149 (1915)*, pp. 3-38, figs. 18).—In this bulletin consideration is given to strawberries, raspberries, blackberries, currants, and gooseberries with reference to establishing plantations, varieties, culture, cost of production, yields, marketing, returns, and profits.

The addition of soft soap to lead arsenate for spraying purposes, D. R. EDWARDES-KER (*Jour. Southeast. Agr. Col. Wye, No. 22 (1913), pp. 359-362*).—The effect of solutions of soft soap upon arsenate of lead suspensions was studied by preparing the mixture in different ways, filtering after allowing to stand for about one-half hour, and determining the soluble arsenic in the filtrate.

The results as here summarized show that the addition of a 1 per cent soap solution to lead arsenate, either homemade or in commercial form, does not lead to any appreciable increase in the amount of soluble arsenic. In the case of the homemade material, however, soap solution must not be used for making up the lead acetate and sodium arsenate solutions in place of water, as not only is there a marked increase in the soluble arsenic but in addition the precipitate is obtained of such a texture and consistency as to render impossible its application by spraying. This precipitate consists of a mixture of lead arsenate and lead soap, a quantity of soluble arsenate equivalent to the lead soap remaining in solution. The addition of soap solution to lead arsenate paste does not, however, lead to the formation of any lead soap nor to an increase in the soluble arsenic.

Spray calendar, F. W. FAUROT (*Missouri Fruit Sta. Circ. 6 (1913), pp. 12, figs. 7*).—This circular contains a schedule for spraying apples and peaches and other stone fruits, together with directions for the preparation of spray mixtures.

New method of obtaining grafted peaches, A. MANARESI (*Staz. Sper. Agr. Ital., 48 (1915), No. 1, pp. 57-60*).—As a result of successful budding experiments in which over 90 per cent of budded trees were secured, the author recommends the use of the so-called June budding method which is frequently employed in propagating peaches in the southern peach districts of the United States, but which does not appear to have been commonly used in Italy.

Testing grape varieties in the Vinifera regions of the United States, G. C. HUSMANN (*U. S. Dept. Agr. Bul. 209 (1915), pp. 157, pls. 10, fig. 1*).—This bulletin gives additional data on the Department's viticultural investigations in the Vinifera regions of the United States, previously reported on in 1910 (*E. S. R., 23, p. 640*), and reports on researches started since that date.

A brief description is given of the twelve experimental vineyards in California, with reference to their purpose, location, soil, and climatic conditions, including weather data secured at each vineyard. Other important data presented in tabular form include cultural data of fourteen American species of grapes whose varieties or hybrids are under test as resistant stocks; the relative growth rating of resistant and direct-producing varieties of grapes under test, including a list of stocks worthy of special mention as having made excellent growth ratings at each of eleven vineyards; resistant varieties making the best growth records in each vineyard; improved American native and Franco-American grape varieties which are being tested on their own roots; the relative behavior and value for different purposes of Vinifera varieties tested by grafting on resistant stocks and by growing on their own roots; and the relative behavior and value for different purposes of improved native American and Franco-American varieties tested.

The investigations as a whole have shown that the adaptability of varieties to soil, climate, and some other conditions can be closely forecasted, but congeniality of stock and scion must be determined by actual test. The best results are obtained where the scion and stock are congenial and both are suited to all the conditions of the environment. Different species used as stocks for the same variety may increase or diminish the vigor and productiveness of the variety and the quality, size, and appearance of the fruit; cause it to ripen earlier or later; and bring about varying results from perfect success to almost

complete failure. A lack of this knowledge has been responsible for heavy losses in reconstituting California vineyards.

Extensive saccharine and acid determinations show a close correspondence between these constituents of the fruit and the congeniality of stock. Similar growth ratings of a variety grafted on different stocks are accompanied by fairly definite percentages of sugar and acid. Congeniality of the variety to the stock materially affects the resistant qualities of the stock.

Quantity and quality of the fruit are usually in opposition on the soils and vines producing most abundantly. Most vine varieties making perfect growth on resistant stocks are found to yield heavier crops than the same variety grown on its own roots. The relative rooting qualities of resistant varieties are an important consideration in the cost of establishing resistant vineyards. Some stocks are suitable for bench grafting while others are especially valuable for vineyard grafting. Of the various stocks tested Riparia, Berlandieri, Champini, and Aestivalis are in most instances congenial to Vinifera varieties. Fruitfulness of these varieties is increased and the time of ripening hastened in comparison with the same varieties grown on other stocks.

Some of the hybrid resistant-stock varieties are making enviable records as stocks under California conditions. Where all the qualities desired can not be found in a hybrid a complex hybrid may yield the desired results. A number of new grape introductions by this Department are proving to be superior to the varieties now commercially grown for certain purposes.

Physiological research on pollen germination in *Vitis vinifera*, E. GARINOCANINA (*Staz. Sperc. Agr. Ital.*, 47 (1914), No. 7, pp. 481-492).—The investigation here reported confirms the author's earlier results (E. S. R., 29, p. 839) with reference to a more or less toxic effect of most spray mixtures commonly used on grapes. In conducting laboratory studies a medium containing 15 per cent saccharose and 2 per cent neutral gelatin, acidulated with tartaric acid solution (1:4,000), was found to be the best for germinating pollen grains. The prolonged action of rain appears to cause the explosion of pollen grains and tubes through the dilution of the glucose-acid fluid. This phenomenon may be reproduced experimentally by germination of pollen grains in distilled water. Temperatures inferior to 14° C. and superior to 35° during the period of fecundation are able to bring about infecundity, the lower temperatures preventing germination and the higher temperatures causing abnormal development of the pollen tubes. The author points out that there should be no indecision as to the use of spray mixtures when choosing between a possibility of pollen sterility and a certainty of mildew attack.

Viticulture in Japan, Y. OINOUE (*Inform. Agr. [Madrid]*, 5 (1915), No. 100, pp. 145-148, figs. 3).—A short descriptive account of viticulture in Japan with special reference to the kinds of grapes grown and those susceptible and resistant to disease.

Some recent experiments on the conservation of grapes in various gases, G. DALMASSO (*Rivista [Conegliano]*, 5. ser., 21 (1915), No. 10, pp. 217-219).—Experiments conducted by the author during 1914 and here briefly summarized indicate that the conservation of grapes in a confined atmosphere of either carbonic acid, deoxygenated air, ozonized air, or pure oxygen is not feasible since deterioration sets in and unpleasant flavors are developed in less than two months' time.

Statistics on the production of grapes and olives in 1914 (*Estadística de las Producciones Vitícola y Olivarera en el Año 1914. Madrid: Govt., 1915, pp. 9*).—This is the usual statistical review relative to the production of grapes, wine, olives, and olive oil in Spain (E. S. R., 31, p. 238).

The methods of reproduction in olive culture, C. CAMPBELL (*Staz. Sper. Agr. Ital.*, 47 (1914), No. 4, pp. 297-307).—A biological discussion relative to the sexual and asexual methods of propagating olives, with special reference to the judicious selection of stock and scion.

Bench rooting of citrus nursery stock, W. R. RALSTON (*Cal. Cult.*, 44 (1915), No. 19, pp. 556, 557, fig. 1; *Univ. Cal. Jour. Agr.*, 2 (1915), No. 8, pp. 292-294, fig. 1).—Investigations conducted by the author at the University of California have shown that the bench root trouble of citrus trees, which has been commonly attributed to the presence of rock or other hard substances beneath the seed when planted, is not due to any external influence, but to the peculiar toughness of the fibrous seed coat, through which the root is unable to penetrate until it has bent and twisted itself to the detriment of the future tree.

It is found that by removing the coat of the seeds very carefully bench root can be totally avoided. This, however, is too expensive a process for nursery practice. Extended experiments have shown that if the seeds are soaked from 36 to 48 hours before planting the bench root will be reduced to 15 per cent of the total number of the seedlings planted.

Notes on the lime and the lemon as sources of citric acid and essential oils, W. R. DUNLOP (*Bul. Imp. Inst. [So. Kensington]*, 13 (1915), No. 1, pp. 66-87).—In these notes the author contrasts the lemon and the lime as sources of citrus products and compares their respective yields and positions in the world's markets. An outline is given of the methods practiced in cultivating limes in the West Indies, including information relative to the commerce in lime products.

The blood orange in the territory of Caltagirone, F. T. COCUZZA (*Ann. R. Staz. Sper. Agrum. e Frutticol. Acireale*, 2 (1914), pp. 1-13).—An account of the blood orange in Caltagirone with reference to its culture, harvesting, and marketing, together with analytical data relative to the dimensions, weight, volume, specific gravity, and chemical analysis.

The cultivation of the hazelnut in the Province of Messina, M. STANCANELLI (*Ann. R. Staz. Sper. Agrum. e Frutticol. Acireale*, 2 (1914), pp. 129-214).—A monograph on the hazelnut (*Corylus avellana*) with reference to its history, economic importance in Sicily, climatic and soil requirements, botany, and varieties, together with details relative to the establishment and care of hazelnut plantations, methods of harvesting, preparation, conservation, and commerce. Economic data are also given relative to the cost of establishing a plantation, cost of production, and returns, including statistics on the commerce of hazelnuts.

An extensive bibliography of cited literature is given.

Dahlia tried at Duffryn, 1914 (*Jour. Roy. Hort. Soc.*, 40 (1915), No. 3, pp. 542, 543).—Data are given on a variety test of dahlias conducted at Duffryn under the direction of the Royal Horticultural Society.

The gardenette or city back yard gardening by the sandwich system, B. F. ALBAUGH (*Cincinnati: Stewart & Kidd Company, 1915, 3. ed., pp. 138, pls. 33*).—A popular treatise on vegetable and flower gardening, in which the author advocates and discusses the use of plant beds with an under stratum of straw or stable litter about 5 in. deep upon which is placed a thin layer of rich, fine, stable manure, covered by another layer of stable litter about 2 in. deep, and then with 4 in. of street scrapings or compost. It is claimed for such beds, which are especially applicable to back-yard gardening, that they mature crops earlier than ordinary garden soils, are well-aerated, and drain off the surplus water well when irrigated.

The use of charcoal as a medium for plant growth, A. APPLEYARD (*Jour. Roy. Hort. Soc.*, 40 (1915), No. 3, pp. 473-475).—A short review of the literature dealing with the use of charcoal by gardeners.

FORESTRY.

The evolution of forest policy, P. DESCOMBES (*L'Évolution de la Politique Forestière*. Paris: Librairie Berger-Levrault, 1914, pp. X+330).—In this work, which comprises the second part of a course in silvonomy, the author briefly reviews the evolution of the forest policy in France down to the end of the nineteenth century, after which an account is given of subsequent activities by various associations and by the State leading to reforestation, with special reference to the establishment of protective forests along mountain slopes.

The term "sylvonomie" as here used bears the same relation to silviculture as agronomy does to agriculture.

The use book, a manual for users of the National Forests, 1915 (*U. S. Dept. Agr., Forest Serv., 1915, pp. 160*).—A fifth revision of the regulations and instructions for the use of the National Forests (E. S. R., 24, p. 548). In this edition, which has been prepared for forest users, those regulations affecting only forest officers and not of interest to the public have been omitted.

International Forestry Congress (*Cong. Forest. Internat. [Paris], 1913, Compt. Rend., pp. 961*).—A report of the general sessions and of the various sections of the International Forestry Congress, held in Paris, June 16 to 20, 1913, under the auspices of the Touring Club of France. The following sections were held: Forest technique or silviculture; forest legislation and economy; forest technology, commerce in wood and wood-using industries; general forestry operations; and the forest in relation to tourists and the esthetic education of the people. Papers by numerous reporters on various phases of these subjects, together with the discussions following and resolutions adopted are included. A bibliography of literature bearing on each section is also given.

Report of the department of forestry of the State of Pennsylvania for the years 1912-13, R. S. CONKLIN (*Rpt. Penn. Dept. Forestry, 1912-13, pp. 493, pls. 14*).—This comprises a report of the commissioner of forestry for the years 1912 and 1913 relative to the administration and management of the state forests and nurseries, nursery investigations, legislation dealing with forest protection and taxation, state and private planting operations, forest surveys, and miscellaneous work, together with a financial statement. Tabular data showing the loss from forest fires and the timber cut in 1912 and 1913 are included.

Progress report of forest administration in the Province of Assam for the year 1913-14, W. F. PERRÉE and A. V. MONRO (*Rpt. Forest Admin. Assam, 1913-14, pp. 2+30+55+5, pl. 1*).—This is the usual account relative to the administration and management of the state forests in the Western and Eastern Circles of Assam, including a financial statement for the year 1913-14. All important data relative to alterations in forest areas, forest surveys, working plans, protection, miscellaneous work, revenues, expenditures, etc., are appended in tabular form.

Progress report of forest administration in the Jammu and Kashmir State for the year 1913-14, W. H. LOVEGROVE (*Rpt. Forest Admin. Jammu and Kashmir [India], 1914, pp. II+26+LIV*).—A report, similar to the above, of the administration and management of the state forests in Jammu and Kashmir.

The flowers of the woods, C. L. GATIN (*Les Fleurs des Bois*. Paris: Paul Lechevalier, 1913, pp. LXXIII+115, pls. 100, figs. 32).—This is the second volume of an encyclopedia for naturalists (E. S. R., 31, p. 143).

Descriptions and illustrations in color are given of about one hundred species of the more common forest flora. Information is given for each species relative to its synonymy, botanical characters, habitat, and uses.

The results of forest-culture experiments, SCHWAPPACH (*Ztschr. Forst u. Jagdw., 47 (1915), No. 2, pp. 65-84*).—A résumé of the more important results

secured from various cultural experiments conducted in the Prussian state forests during the past 40 years. Tabular data are grouped and discussed with reference to the following phases: The effect of various cultural methods, the influence of various combinations of trees, a mixed stand of *Pinus silvestris* and *P. rigida* as compared with a pure stand of *P. silvestris*, the effect of various combinations of trees upon the resistance against crushing by snow, and the effect of early strong thinning on the development of spruce stands.

Some Irish larch plantations, J. H. WADDINGHAM (*Jour. Bd. Agr. [London]*, 22 (1915), No. 3, pp. 231-235).—In continuation of a previous article (E. S. R., 31, p. 240) growth measurements are given for sample plats in a larch plantation. The trees on different plats vary from 27 to 58 years of age.

Pine tree culture in Nordland, F. LINDBERG (*Skogsvårdsför. Tidskr.*, 1915, Sup. 2, pp. 48, figs. 22).—An account is given of methods of reforesting pine lands both by seeding and by planting.

Hevea tapping results, Experiment Station, Peradeniya, 1911-1913, T. PETCH (*Dept. Agr. Ceylon Bul.* 12 (1914), pp. 28, pls. 2).—A progress report on tapping experiments with Hevea rubber started in 1912, including a brief summary of previous work. The experiments are designed to show the difference in yield and the effect on the trees of various systems of tapping which differ in their time interval or space interval. Thus far no definite conclusions are drawn.

Hevea tapping results, Experiment Station, Peradeniya, 1914, T. PETCH (*Dept. Agr. Ceylon Bul.* 17 (1915), pp. 16, pl. 1).—A further progress report on the above noted investigation.

Scientific tapping experiments with Hevea brasiliensis, A. W. K. DE JONG (*Dept. Landb., Nijv. en Handel [Dutch East Indies], Meded. Agr. Chem. Lab.*, No. 10 (1915), pp. 83, figs. 39).—The first part of this work describes the various experiments included in a comparison of tapping methods on a number of plats of Hevea rubber trees. The second part describes similar comparative tests on individual Hevea trees.

Among the many results from the investigations as a whole it was found that the method of making the cuts by individual tappers affected the yield of rubber considerably. The thickness of the bast strip removed as well as the direction of the cut, that is from above, below, or vice versa, had no material influence on the yield of the cut. The maintenance of a continuous flow of latex depended more on the restoration of capillary action than upon any peculiarity of the latex itself. Neither the evaporation of the latex nor the drying out of the bast had much effect on yield from cuts that were opened daily.

Where cuts one above the other were not more than 50 cm. apart, the lower cut averaged the greater yield of rubber. For greater distances than this no effect was noticeable. Wounding the tree resulted in a stronger local formation of rubber. Young bast gave more rubber than old. A left-hand cut appeared to have some advantage over a right-hand cut, but there was very little difference in yield between a "V" cut and a left-hand cut.

A test of cuts of various slopes showed that the cut making the smallest angle with the main tapping channel uses up the greatest amount of bast without giving a corresponding increase in rubber yield. Cuts made in a vertical direction gave only about half the yield of a cut making an angle of 50° with the tapping channel. It made no material difference whether cuts were renewed on the upper or the lower side. The opening of one cut above another cut or alongside another cut appeared to affect the yield of the first cut, provided the distance between the two cuts was not great. No effect on yield was noticed from cuts made on opposite sides of the tree.

Experiments in which cuts were renewed twice a day showed that the removal of latex from the capillaries of *Hevea* trees takes place locally. The equilibrium of the capillary action is broken down about four hours after the first renewal. Examinations of ringed trees showed the presence of tyrosin or the conversion of tyrosin into tyrosinase in the latex above the ring, whereas beneath the ring tyrosinase alone was found. Isolated patches of bast were capable of forming rubber. The circumference of *Hevea* trees at 10 cm., 85 cm., and 1.35 meters height averaged as 1.6:1.13:1.

Tapping and the storage of plant food in *Hevea brasiliensis*, L. E. CAMPBELL (*Dept. Agr. Ceylon Bul. 16 (1915), pp. 26, pls. 6, figs. 8*).—The author presents the results in detail of a study of two trees from the same clearing which were planted in 1906 and tapped first in July, 1913. They were tapped for six months on the full herringbone system, the tapping took place once every third day, and one side only of the tree was tapped.

The results of the study as a whole lead to the conclusion that the effects of tapping on the trees here discussed were almost purely local. Starch was withdrawn from the wood immediately behind the cut and also partially from narrow zones of bark below and on each side of the tapped area. These zones did not exceed 1.5 in. in breadth and in most cases the breadth was considerably less than this. The starch content of the bark was normal in most cases right down to the top of the tapped area. Excepting for the localized withdrawal of starch in the neighborhood of the tapping cut the food supply had not disappeared from below the tapped area.

Attention is called to the fact that care was taken in tapping not to cut the cambium layer. Where careless or heavy tapping has been employed the tapping cut extends down to, or nearly down to, the wood, thus bringing about a complete severance of the channels of food transport at that place. In view of this localized effect of not too deep tapping it is suggested that by changing tapping from one part of the tree to another at intervals, the resting period of each area so tapped is nearly as effective as if the whole tree were rested.

The tapping of an old *Hevea* tree at Henaratgoda, T. PETCH (*Dept. Agr. Ceylon Bul. 13 (1914), pp. 4*).—A further report on a high-yielding *Hevea* tree at Henaratgoda (E. S. R., 26, p. 444). The tapped tree measured 117 in. in circumference at 3 ft. from the ground in August, 1914. It has been tapped at short intervals over a period of 4 years, 9 months, with a total yield of 392 lbs. 7 oz. of dry rubber of which 220 lbs. 7 oz. was secured from renewed bark.

Notes on the history of the plantation rubber industry of the East, T. PETCH (*Ann. Roy. Bot. Gard. Peradeniya, 5 (1914), No. 7, pp. 433-520*).—A compilation from the literature dealing with rubber culture, chiefly in Ceylon. References to cited literature are given.

The naval stores industry, A. W. SCHORGER and H. S. BETTS (*U. S. Dept. Agr. Bul. 229 (1915), pp. 58, pls. 11, figs. 11*).—This bulletin reviews the present status of the naval stores industry and the progress which has been made in improving the methods of collecting and distilling gum. Information is also given on the supply of timber available for turpentine operations.

The subject matter is discussed under the following general headings: Need for improved methods, history of the industry in the United States, statistics of production, commercial utilization of products, formation and flow of resin in the living tree, principles underlying the distillation of crude gum, commercial methods of collecting crude gum, relative yields secured from cups and boxes, relative amounts of scrape formed by the box and cup systems, relative yields from different depths and heights of chipping, effect of turpentine operations on timber, quality of gum from boxed and cupped timber, commercial distillation of crude gum, French methods of collecting gum, French distillation

methods, comparison between direct and steam-heated stills, the supply of longleaf pine for turpentine operations, possibilities of western pines as a source of naval stores, special problems investigated, Arizona and California western yellow pine, suggestions for specifications, packing naval stores, cost estimates on a 20-crop turpentine operation, publications relating to the naval stores industry, and patents relating to the naval stores industry.

Records on the life of treated timber in the United States, H. F. WEISS and C. H. TEESDALE (*Proc. Amer. Wood Preservers' Assoc.*, 11 (1915), pp. 501-509).—A tabular compilation of data showing the life of treated timber in the United States. Various records are given for cross-ties, piling, bridge timbers, mine timbers, poles, posts, and paving blocks.

DISEASES OF PLANTS.

Notes on plant diseases in Virginia observed in 1913 and 1914, H. S. REED and C. H. CRABILL (*Virginia Sta. Tech. Bul.* 2 (1915), pp. 37-58, figs. 17).—Descriptions are given of diseases observed on alfalfa, apple, bean, maple, peach, plum, and potato.

Among the alfalfa diseases of unusual occurrence the authors note yellow top, a disease considered identical with that previously reported in New York (E. S. R., 20, p. S46), and white spot, in which infected plants show white semitranslucent spots on the leaves. Both of these diseases, the causes of which are undetermined, may at times induce considerable injury.

Among apple diseases the authors report the occurrence of blister canker, collar blight, crown gall, and sunburn. In addition a number of unusual troubles are described, the definite causes of which are unknown. Among these are a form of tumor to which the name flap tumor is given. This disease is characterized by peculiar flap-like growths that are developed covering wounds due to various causes. A brief notice is given of punky pulp of Ben Davis, in which the fruits are said to be smaller than normal, punky, brittle, and entirely unfit for consumption. This trouble is believed to have been due to the dry weather of 1914. Root rot of apple trees, which is said to be causing considerable loss, is described, the disease being accompanied by a white mycelium, but as yet no sporophores of the fungus have been found present. A skin crack of the York Imperial apple is described, which is believed to be due to physiological disturbances such as sudden increase of water supply. In this trouble small sunken cracks appear in the skin of the fruit. Usually the cracks are less than 2 mm. in length, but sometimes they are larger and a number of them become confluent, giving the fruit a grayish scabby appearance. Later a soft black rot, caused by *Alternaria mali*, attacks the fruit through the tissue underneath the cracks. Another apple trouble, which is called the York spot, is confined to the variety York Imperial. This in the early stages resembles the disease commonly called Jonathan or Baldwin spot, but later the fruit exhibits sunken, dark green spots, beneath which the tissue is brown-walled, the areas infected resembling the injury due to hail. Later in the season badly infected fruits show soft rot, probably due to saprophytic fungi. No organisms have been grown from the spots until soft rots have set in. The cause of this disease has not been definitely determined.

A brief account is given of a thrombotic disease of silver maple, in which the leaves turn yellow, growth is poor, and the trees become defoliated earlier than usual. An examination of infected limbs showed that the wood was streaked with green, resembling the condition described by Rankin as due to *Acrostalagmus* sp. (E. S. R., 33, p. 249).

Peach scab, plum rust, Rhizoctonia, tip burn, wilt, and hollow heart of potatoes are also briefly noted.

Report of the botanist and mycologist, T. PETCH (*Rpt. Dept. Agr. Ceylon, 1912-13, pp. C7-C9*).—This report includes the mention of Hevea canker (*Phytophthora faberi*), gray blight (*Pestalozzia palmarum*), and bird's eye spot (*Cercospora theae*) of tea; a disease of stored coconuts, one of plantains, and one of indigo; *Rosellinia bothrina* attacking camphor, also this tea root disease and another, *Poria hypolateritia*, attacking *Tephrosia candida*; a fungus disease of mangosteens; bacterial wilt of tomato; two stem diseases, a root disease, a fruit rot, and two leaf diseases, *Melampsorella ricini* and *Cercosporina ricinella*, of castor oil plant; *Erysiphe polygona* on peas; a Nectria stem canker of *Acacia decurrens*; *Phragmidium disciflorum* on rose; *Plasmopara viticola* on grape; *Cladosporium* on sorghum; and a Merulius dry rot on wattle in walls of bungalows.

A list of recent publications is given, as is also a brief account of recent botanical work done by the staff of the herbarium.

Notes upon Washington fungi, J. G. HALL (*Phytopathology, 5 (1915), No. 1, pp. 55-58, pls. 2*).—From a study of Coryneum-like structures on apple and Sambucus, the author is convinced of their identity. Material submitted to Dr. Roland Thaxter resulted in the identification of the fungus as *Hendersonia diploidioides*. In connection with this fungus the author reports an ascospore stage which is considered to be *Othia amica*.

Two new species of fungi are described, *Neottiospora yuccaefolia* on withered or dying Yucca leaves and *Turecniella juncoidea* on dead culms of Juncus.

The temperature relations of some fungi causing storage rots, ADELINE AMES (*Phytopathology, 5 (1915), No. 1, pp. 11-19*).—The author has made a study of the thermal relations of some of the fungi causing storage rots, those selected for the investigation being *Glomerella rufomaculans* and *Cephalothecium roseum* from apples, *Thielaviopsis paradoxa* from pineapple, *Penicillium digitatum* from orange, *Rhizopus nigricans* from sweet potato, and *Monilia fructigena* from plums.

The results obtained show that *Monilia* and *Penicillium* germinate at 0° C., but growth is very slow. The other fungi do not develop below 5°, but if growth is started at a higher temperature it can continue at this temperature. Aside from *Rhizopus* none of the organisms were able to germinate above 36°. The optimum temperature of growth for *Monilia* and *Penicillium* is 25°, *Thielaviopsis*, *Glomerella*, and *Cephalothecium* 30°, and *Rhizopus* 36°. The thermal death point of *Rhizopus* is 60°, of *Penicillium* 58°, and of the remaining fungi between 51° and 53°.

The results indicate that in refrigerating experiments, temperatures as near zero as possible must be maintained if the development of rot producing fungi is to be entirely avoided.

Further studies on the specialization of *Uromyces caryophyllinus*, E. FISCHER (*Mycol. Centbl., 3 (1913), No. 4, pp. 145-149*).—The author reports his recent experimentation, held to show that *U. caryophyllinus* from the canton of Valais is capable of infecting *Saponaria ocymoides* as well as *Tunica prolifera*. Previously it was found (E. S. R., 28, p. 149) that *U. caryophyllinus* from the vicinity of Heidelberg lived only on *T. prolifera*, and only in exceptional cases passed over to *S. ocymoides*.

It is concluded that the specialization of this fungus is not the same in Valais as in Baden.

The specialization of *Puccinia pulsatillæ*, E. FISCHER (*Mycol. Centbl., 3 (1913), No. 5, pp. 214-220*).—In experiments testing the capability for infection by teleutospores of *P. pulsatillæ* developed on *Anemone montana*, more or less

complete positive results were obtained with the hosts *A. vernalis*, *A. pratensis*, and *A. pulsatilla*, but only negative results with *A. alpina*, *A. sylvestris*, and *Atragene alpina*, which are thought to present examples of genuine immunity to *P. pulsatillæ* grown on *A. montana*.

The specialization here noted, as connected with systematic classification, is contrasted with the geographical specialization in the case noted above by the same author, the two types of specialization being discussed.

Overwintering of cereal rusts in uredospore form, L. MONTEMARTINI (*Riv. Patol. Veg.*, 7 (1914), No. 2, pp. 40-44).—Noting the infection of wheat by Puccinia in the uredospore stage, passing over from grasses in warm autumn weather, the author also records the germination at Stradella and Pavia of uredospores developed on volunteer and other cereals after subjection for some days to temperatures several degrees below the freezing point.

Rust attack of winter cereals, L. HILTNER (*Prakt. Bl. Pflanzenbau u. Schutz, n. ser.*, 12 (1914), No. 7, pp. 81-84).—It appears from numerous reports received by the author that rust is present in all parts of Bavaria and also in neighboring regions in greater or less severity, affecting varieties of rye as well as wheat. The matter is discussed with reference to varietal resistance and the influence, in this connection, of phosphoric, nitrogenous, and other fertilizers, a right use of these with suitable cultivation appearing to increase resistance.

Yellow rust, which is now said to attack the squarehead variety of wheat, is not controlled by any means yet available. Earlier sowings of rye suffer less from rust than do later plantings. The kind of crop previously grown on the land is said to exert considerable influence. Reports indicate also a connection between abrupt changes in temperature and rust attack.

Treatment of winter grain with corrosive sublimate, L. HILTNER (*Prakt. Bl. Pflanzenbau u. Schutz, n. ser.*, 12 (1914), No. 8-9, pp. 85-89).—Discussing the results of a large number of practical tests in treating seed grain for autumn sowing, as reported from various localities, the author states that steeping seed wheat in the Sublimoform solution and rye in corrosive sublimate preparation materially reduced injury, not only from stinking smut, etc., but also from snails and mice, but that loose smut of wheat was not prevented by such treatment.

Chinosol and formaldehyde as protection against *Fusarium* in cereals, L. HILTNER (*Prakt. Bl. Pflanzenbau u. Schutz, n. ser.*, 12 (1914), No. 7, pp. 77-80, fig. 1).—The author has confirmed, with field tests, the results obtained by Gentner (*E. S. R.*, 28, p. 846). The sublimate solution used to steep the seed grain afforded complete protection. Formaldehyde was not so satisfactory. Chinosol is regarded as unsatisfactory in this connection.

Limitation and management of grain for seeding, L. HILTNER (*Prakt. Bl. Pflanzenbau u. Schutz, n. ser.*, 12 (1914), No. 8-9, pp. 90, 91).—Noting the special importance, at this time, of economical management of the available supply of grain for seeding purposes, the author urges careful selection of seed for germinability, previous treatment of the seed grain with approved solution, and avoidance of too thick sowing.

Use of rusted grain for seed, L. HILTNER (*Prakt. Bl. Pflanzenbau u. Schutz, n. ser.*, 12 (1914), No. 8-9, p. 91).—Since rust, unlike smut, is not transmitted to the crop through diseased seed, the use of grain from rusted crops is not regarded as dangerous. Cases where yellow rust was particularly severe and where also the output of grain was much reduced were found to show severe attack from foot or stalk disease, or from diseases due to other causes.

Dry spot of oats, L. HILTNER (*Prakt. Bl. Pflanzenbau u. Schutz, n. ser.*, 12 (1914), No. 3-4, pp. 28-41, fig. 1).—The general outcome of the experiments and observations here noted is the confirmation of the view that dry spot of oats is

the result of nutritional deficiencies or disturbances, or both, and that the correction of these tends to restore the normal condition and productiveness of the plant. Measures apparently effective in this connection are protection from insect pests and frequent spraying with iron salts.

Hiltner's experiments on the control of dry spot of oats, T. A. C. SCHOEVEERS (*Tijdschr. Plantenziekten*, 20 (1914), No. 2, pp. 69-73).—This is mainly a brief review of the work of Hiltner, above noted.

Some observations on ordinary beet scab, B. F. LUTMAN and H. F. JOHNSON (*Phytopathology*, 5 (1915), No. 1, pp. 30-34, figs. 4).—From a study of eight organisms isolated from scabby beets from various parts of Vermont the authors were led to the conviction that the forms were not only identical, but were the same as the organism *Actinomyces chromogenus*, which causes potato scab. This same organism is present in many soils and on many plants, but in explanation of the scabbing of the potato and the beet, in connection with the immunity of many other root and tuber plants, the authors hold that the reason undoubtedly lies in the fact that some sort of a cambium is so close to the surface as to be affected by the toxic substances produced by these bacteria. The parasitism of the organism is said to be dependent on a particular type of root or tuber structure, and when this is not present it is forced to live as a saprophyte.

Beet scab, GRIMM (*Prakt. Bl. Pflanzenbau u. Schutz*, n. ser., 12 (1914), No. 8-9, pp. 100-102).—Beet scab is said to have caused loss in several localities, particularly in connection with the wet season of 1913. The disease seems to be due rather to bad nutritive conditions than to parasites primarily. The use of seed in propagation and the employment of potassium, superphosphate, and ammonia in fertilizers is recommended.

Rearing beet nematodes on agar, E. BERLINER and K. BUSCH (*Biol. Centbl.*, 34 (1914), No. 6, pp. 349-356, pl. 1).—A brief account is given of the rearing of nematodes (*Heterodera schachtii*) on rootlets of various seedlings grown on agar, and of the changes and activities observed. None developed apart from the rootlets or survived long after the exhaustion of the reserve material which was brought forward from the egg stage.

Root scab and other celery diseases, H. M. QUANJER and N. SLACTER (*Tijdschr. Plantenziekten*, 20 (1914), No. 1, pp. 13-27, pl. 1).—The authors' conclusions from studies as described with rust or scab of celery root are said to have confirmed those of Klebahn (E. S. R., 22, p. 746) that *Phoma apicula* is the cause of this disease. It is thought, however, that infection with this fungus from the seed is rather exceptional, the rule being that the infection is due to material in the soil, fertilizers, etc. Formalin was a very helpful treatment in this connection for the seed bed.

As regards *Septoria apii*, associated with celery leaf spot, Klebahn's conclusion regarding the agency of the seed as a carrier of infection was confirmed. This trouble also was largely prevented by the formaldehyde treatment and benefited by the use of Bordeaux mixture applied to the leaves.

Some new bacterial diseases of legumes and the relationship of the organisms causing the same, T. F. MANNS (*Delaware Sta. Bul.* 108 (1915), pp. 44, pls. 20, fig. 1).—An account is given of a disease of sweet pea due to *Bacillus lathyri*, a previous account of which has already been noted (E. S. R., 29, p. 352); and similar diseases upon clovers, garden beans, and soy beans are described.

The disease on sweet pea is apparently widely spread, having been reported in England, Massachusetts, Maine, New York, Delaware, and also in Ireland. Previous investigators have referred to a number of causes, but the investiga-

tions of the author indicate that it is of a bacterial nature, and that the same organism produces somewhat similar diseases on various species of clover, on garden beans, and on soy beans, although only one variety of soy beans grown at the station shows much injury. The disease is said to be most active during the flowering period of the host, and at times almost entirely destroys the crop. The season of heavy dew appears to be a time which favors infection. The morphology, cultural characters, physical and biochemical features, and pathogenicity of the organism are described at length.

A bibliography is appended.

The life history of *Ascochyta* on some leguminous plants, II, R. E. STONE (*Phytopathology*, 5 (1915), No. 1, pp. 4-10, fig. 1).—In a previous publication (E. S. R., 28, p. 845) the author reported *Mycosphaerella pinodes* as the perfect stage of *A. pisi*, and *A. lethalis* as a part of the life cycle of *M. lethalis*.

In the present publication a description is given of *A. lathyri* from the grass pea (*Lathyrus sativus*), which is associated with *M. ontariensis* n. sp. The *Mycosphaerella* follows the *Ascochyta* in the field, and in inoculation experiments typical *Ascochyta* developed on the plants, followed by *Mycosphaerella*, which is indistinguishable from the original material. In all cases check plants remained free from the disease.

Notes are given of conditions for ascospore development in *M. pinodes* and *M. ontariensis*.

The Rhizoctonia lesions on potato stems, F. L. DRAYTON (*Phytopathology*, 5 (1915), No. 1, pp. 59-63, pl. 1, fig. 1).—A report is given of a study of the dark brown lesions occurring on the underground main stems and tuber-bearing stolons of the potato, and generally considered as due to the presence of Rhizoctonia.

The result of the investigation showed the presence of mycelium in the lesions and the permeation of nearly all the tissues, which leaves little doubt that Rhizoctonia is the cause of the trouble. The invasion and plugging of the vascular tissues, diverting the food material going from the leaves to the actively growing parts, account for the production of undersized tubers or none at all. By the stopping of the upward current through the plugging of the vessels, especially in dry weather, a curling of the leaves may be produced, and this is nearly always a symptom associated with the disease.

Puccinia endiviæ and rust of prickly lettuce, L. MAFFEI (*Riv. Patol. Veg.*, 7 (1914), No. 2, pp. 45, 46).—It is stated that the "scariola," claimed by Pantanelli and Cristofolletti (E. S. R., 31, p. 746) to be attacked by *P. endiviæ*, is apparently not *Lactuca scariola*, but endive (*Cichorium endivia*).

Protascus colorans, the source of yellow grains in rice, P. C. VAN DER WOLK (*Mycol. Centbl.*, 3 (1913), No. 4, pp. 153-157, pl. 1).—The author has investigated the subject of yellow grains in rice kept long in bulk, which is said to cause considerable loss and disturbance in marketing the rice exported from the Indies to Europe.

The trouble is said to be caused by a fungus, hitherto undescribed as to genus and species, which the author has named *P. colorans*, which is said to show a very variable number of ascospores (2 to 15), and which is otherwise discussed. The best development of this fungus requires a very small moisture content in the rice grains, experiments often failing to develop the organism on account of its low tolerance of humidity. Pigment formation is probably a phenomenon of the dying away of the fungus, which fact may explain why it is very difficult to rear this mold from the yellow grains themselves, and this also in turn may explain the rise of a brooding theory of this rice injury.

The simplest means of prevention is first disinfection, and second the maintenance of absolute dryness in the grains, which requires exclusion of insects therefrom and frequent heating.

Rust of fruit trees, A. DESMOULINS (*Prog. Agr. et Vit. (Ed. l'Est-Centre)*, 36 (1915), No. 11, pp. 253-255).—Giving results of recent observations and tests on *Coryneum* rust of peach, apricot, and cherry in the Rhone Valley, the author describes a treatment with Bordeaux mixture rendered adhesive by the addition of molasses (1 kg. per hectoliter). This is said to have proved effective and practical.

Influence of atmospheric conditions on the appearance of downy mildew, J. CAPUS (*Prog. Agr. et Vit. (Ed. l'Est-Centre)*, 36 (1915), No. 9, pp. 198-200).—The author gives the results of observations covering several years on the relations between atmospheric conditions and the two early developmental phases of downy mildew.

Infection (penetration of the tissues by the germinative tubes from zoospores) occurs only following precipitation, which may be as small as 1 mm. Contamination (passing out of the stage within which copper fungicides can destroy the fungus) may follow infection immediately, or it may be delayed for several days by unfavorable conditions, such as cold, or by precipitation, which appears to prolong the period during which spraying is effective. The primary invasion or attack is that which first appears in spring (originating in overwintered material), while secondary outbreaks are due to conidia formed as the result of primary or later outbreaks.

It is found to be an unsafe practice to spray early and then await the appearance of the mildew on the newly developed (and hence unsprayed) leaves, to make a second application. In case of both primary and secondary outbreak, the treatment becomes ineffective within a day or two after a rain.

Oidium of oak and grape, L. RAVAZ (*Prog. Agr. et Vit. (Ed. l'Est-Centre)*, 36 (1915), No. 4, pp. 86-89).—Giving a brief résumé of some observations on Oidium of oak and of grape by Pantanelli, the author directs attention to some preferences and habits noted in regard to portions attacked as regards age of parts exposed, structure, cell content, turgescence, and nutrition.

Report of the plant pathologist, G. L. FAWCETT (*Porto Rico Sta. Rpt. 1914*, pp. 27-30).—An outline is given of work in progress, which included testing various forms of Bordeaux mixture and some studies on diseases of coffee, cacao, and citrus trees.

The experiments with fungicides show that homemade Bordeaux mixture, if properly prepared, is cheaper and as efficient as any of the proprietary forms tested.

Among the coffee diseases reported upon, experiments were carried on to test the relative resistance of different varieties of coffee to the fungi *Stilbella flavida* and *Pellicularia koleroga*. Some difference in susceptibility to these fungi was noticed on the part of different varieties, although complete resistance was not observed.

Notes are given of a new fungus disease of cacao, which is believed to be due to a species of *Corticium* which has not yet been definitely determined. In addition to occurring on cacao, the fungus also attacks and kills coffee tree branches and has been found parasitic on grapefruit branches, although in the latter case it is thought to have been associated with the presence of a wild vine growing over the tree. Attention is called to the fact that *Phytophthora faberi*, the cause of black rot in the pods of cacao, has never been found in Porto Rico, but that *Spicaria (Fusarium) colorans* has been isolated from diseased tissues.

The author briefly calls attention to the black rot of citrus fruits due to *Diplodia natalensis*.

The known distribution of *Pythiacystis citrophthora* and its probable relation to mal di gomma of citrus, H. S. FAWCETT (*Phytopathology*, 5 (1915), No. 1, pp. 66, 67).—In a previous publication the author reported this fungus as being the causal agent of one form of lemon gummosis in California (E. S. R., 30, p. 51). Since that time the fungus has been isolated from diseased bark from nearly all the important citrus growing localities of California.

In June, 1913, it was isolated from diseased bark of orange trees that appeared to be affected with typical mal di gomma, or foot rot, as it is known in California. Inoculations and cultures of this fungus were made in large crown roots of old orange trees, and in nine months they developed diseased areas which resembled the beginning stages of mal di gomma. The orange bark is said to be somewhat more resistant than lemon bark and reacts somewhat differently toward the fungus. This, it is believed, explains the difference in appearance of mal di gomma and lemon gummosis in California.

In addition to the occurrence of this fungus in California, the author reports having observed it in Florida, Cuba, and the Isle of Pines, and claims to have record of it in southern Europe and in Brazil.

The citrus root nematode (*Tylenchulus semipenetrans*) in Florida, E. NELSON (*Phytopathology*, 5 (1915), No. 1, pp. 72, 73).—The author reports having examined 35 orange trees, 5 of which had healthy foliage and showed no infestation with nematodes. The leaves of the remaining 30 were affected with a form of chlorosis known as frenching. Twelve of the 30 affected trees showed the presence of root nematodes, but the remaining 18 showed no infestation.

The author believes that further investigations and experiments are necessary before any conclusions can be drawn as to the connection of this nematode with the frenching of citrus trees.

Storm and drought injury to foliage of ornamental trees, C. HARTLEY and T. C. MERRILL (*Phytopathology*, 5 (1915), No. 1, pp. 20-29, figs. 3).—Detailed observations are given showing the effect of drought and storms in the District of Columbia and several places in Pennsylvania and New Jersey.

In the District of Columbia the June and July rainfall in 1913 was much below normal and this period was followed on July 30 by a hail storm, heavy rain, and wind of high velocity. It is said that at least 25 per cent of all Norway maple trees in the District of Columbia were noticeably affected by the drought. Other maples suffered somewhat, but less severely, and drought injury was also noticed on oaks and other trees. The effect of the storm mentioned above was quite pronounced on many different kinds of trees, but so far as observed the drought preceding the storm was not in any way responsible for the storm injury. The leaves of the sugar maple were found most susceptible to injury by the high velocity of the storm. The damage was similar to that produced by drought in that the margins of the leaf and the area between the veins were affected, but the material difference between the two forms of injury is that drought injury is more closely confined to the leaf margins, while storm injury tends to affect areas situated between the veins as well.

New hosts for some forest tree fungi, J. R. WEIR (*Phytopathology*, 5 (1915), No. 1, pp. 71, 72).—The author reports the occurrence of *Herpotrichia nigra*, or its related form, *Neopeckia coulteri*, on the giant western red cedar, grand fir, western yew, and red or Douglas fir. It is also reported on the western white pine, the Engelmann spruce, mountain hemlock, lodgepole pine, white barked pine, and alpine fir. *Fomes laricis* is reported for the first time on *Pinus monticola*, *Abies grandis*, and *Tsuga mertensiana*. *F. igniarius* was found on *Rhamnus purshiana* and *Sambucus glauca*. *Armillaria mellea* is reported as attacking *Taxus brevifolia*, and *Polyporus lucidus* was found growing on the mountain hemlock. The mountain hemlock has in many places been seriously

attacked by *Razoumofskya tsugensis*. *Echinodontium tinctorium* is also said to be abundant on this species of tree, and a collection of it was made from the Engelmann spruce.

Notes on the chestnut bark disease, J. T. ROGERS and G. F. GRAVATT (*Phytopathology*, 5 (1915), No. 1, pp. 45-47).—Observations are reported on the infection of the chinquapin in Virginia by the chestnut bark fungus (*Endothia parasitica*). Inoculation experiments indicate that the chinquapin is no more resistant to the girdling growth of the blight fungus than is the chestnut. However, as the former is not so subject to insect and other injuries as is the chestnut, this is considered the reason for its freedom from disease in the field.

Notes are given of observations of the spread of the chestnut bark disease over a small area, observations having been made on a plat containing 140 chestnut trees in May, 1913, September, 1913, and May, 1914. The average rate of diameter growth of the disease cankers was found to be 6.35 in. for the year. At this rate of growth a number of years would be required for the girdling of a large tree by a single canker.

Chestnut blight in Nebraska, R. G. PIERCE (*Phytopathology*, 5 (1915), No. 1, p. 74).—The author reports having observed the chestnut bark fungus (*Endothia parasitica*) at two places in Nebraska in 1914. It was on chestnut trees that had been shipped to nurseries from the East.

Notes on chestnut fruits infected with the chestnut blight fungus, CAROLINE RUMBOLD (*Phytopathology*, 5 (1915), No. 1, pp. 64, 65).—In order to test the possible infection of chestnut burs and nuts the author collected from a blight-infected orchard fresh, sound nuts and burs containing nuts. These were fumigated and placed in paper bags, kept in a warm room, and later examined.

More than one-third of the nuts were found infected, those remaining in the burs being especially attacked. The fungus was found to have grown from the infected bur through the shell at the base of the nut, where there is close connection between the two and where the hard shell of the nut matures last.

From the comparative ease with which the nuts and burs were infected the author thinks it probable that an occasional infected chestnut might be collected at harvest time, and that this would be a possible means of the dissemination of the disease, as suggested by Collins (E. S. R., 30, p. 543).

Notes on Rhizoctonia, C. HARTLEY and S. C. BRUNER (*Phytopathology*, 5 (1915), No. 1, pp. 73, 74).—The authors report having found Rhizoctonia very commonly present in damped-off pine seedlings, and this is believed to be the chief cause of the loss in beds of *Pinus ponderosa*. The parasite spreads for several weeks after germination of the pines and appears to produce larger single patches of dead seedlings than any other damping-off organism observed in western nurseries, and also to attack seedlings too old to be killed by *Pythium debaryanum* or *Fusarium moniliforme*.

Observations were made on a number of weeds that come up in areas where the pine seedlings have been killed by the fungus, and an examination of the soil showed that Rhizoctonia is very commonly present in groups of *Ambrosia psilostachya*. On account of the perennial habit of this ragweed it is considered an ideal host for the parasitic strains of Rhizoctonia to winter over on.

Observations on *Hirneola auricula-judæ*, M. J. LE GOC (*Proc. Cambridge Phil. Soc.*, 17 (1913), No. 3, pp. 225-228).—The Jew's ear fungus is said to be of very wide distribution and of frequent occurrence in the neighborhood of Cambridge, England, where it is found on elder bushes both living and dead; also on dead portions of elm in moist places.

Cultures were made and studied. Penetration of wood by the fungus is very rapid, its path at first being the vessels and tracheids, with penetration through the pits and more frequent branching in the medullary rays. Later the fungus

encroaches upon the cell walls, the xylem becoming delignified and the walls penetrated and consumed. This change renders the tissue spongy and crumbly, examination showing it to consist more of the fungal hyphæ than of the original material of the tree.

Further observations on *Hirneola auricula-judæ*, M. J. LE GOC (*New Phytol.*, 13 (1914), No. 4-5, pp. 122-133, figs. 9).—Concluding a fuller account covering later study than that noted above, the author states that germination of the spores of the Jew's ear fungus takes place readily and occurs even on the fructifications if these are kept moist. Basidiospores developed in nutritive solutions, but less frequently in water. Conidia are produced rarely and only in distilled water, so far as noted. Pure cultures of the fungus grow readily on elder, lime, and elm wood, producing rudimentary fructifications. Penetration, delignification, and almost complete consumption of the wood quickly follow natural infection with the fungus. Inoculations on healthy living twigs of elder were often successful, the hyphæ penetrating slowly at first, but finally killing the twigs.

Some observations on abortive sporophores of wood-destroying fungi, J. R. WEIR (*Phytopathology*, 5 (1915), No. 1, pp. 48-50).—Attention is called to the presence of hard, brown, sterile, abortive sporophores which are commonly observed on birches and alders. The author reports having collected these structures from the paper birch, associated with the fertile sporophores of *Fomes igniarius*. Abortive fruiting structures are also said to be occasionally formed by *Echinodontium tinctorium* on old and badly decayed hemlock, and similar structures are produced by *Trametes pini* on the western white pine.

ECONOMIC ZOOLOGY—ENTOMOLOGY.

Zoological philosophy: An exposition with regard to the natural history of animals, J. B. LAMARCK, trans. by H. ELLIOT (*London: Macmillan & Co., Ltd.*, 1914, pp. XCII+410; rev. in *Nature* [London], 94 (1915), No. 2363, pp. 639, 640).—This is a translation of the author's *Philosophie Zoologique*, which was published in 1809, half a century before Darwin's *Origin of Species*, and is one of the evolution classics.

Some Canadian rodents injurious to agriculture, N. CRIDDLE (*Agr. Gaz. Canada*, 2 (1915), No. 2, pp. 110-114, fig. 1).—This is a brief account of the more important Canadian rodents and means for their control.

How plague may be carried from place to place (*Pub. Health Rpts.* [U. S.], 30 (1915), No. 13, pp. 891, 892).—This article records the finding of a live plague-infected rat at Seattle, Wash., in a large box containing plants imported from Yokohama, Japan.

Rat proofing the public docks of New Orleans, H. P. LETTON (*Pub. Health Rpts.* [U. S.], 30 (1915), No. 8, pp. 545-555, pls. 4, figs. 5).—A report on the possibility and cost.

The economy of ground squirrel destruction, J. D. LONG (*Pub. Health Rpts.* [U. S.], 29 (1914), No. 50, pp. 3317-3321).—The author points out the various advantages resulting from the destruction of ground squirrels in California.

Cimex pipistrelli, the intermediate agent in the transmission of trypanosomiasis of bats; the nonpathogenicity of *Trypanosoma vespertilionis* for laboratory animals, E. PRINGAULT (*Compt. Rend. Soc. Biol.* [Paris], 76 (1914), No. 19, pp. 881-884; abs. in *Rev. Appl. Ent.*, 2 (1914), Ser. B, No. 11, pp. 173, 174).—The author's experiments indicate that this bug is the intermediate host of *T. vespertilionis* and that this trypanosome is not pathogenic for mice, rats, guinea pigs, or rabbits.

The bird book, C. A. REED (*Garden City, N. Y.: Doubleday, Page & Co., 1915, pp. 472, figs. 1425*).—Brief descriptions are given of 768 North American birds and additional descriptions of varieties. More than 700 North American birds are illustrated in natural colors and several hundred photographs are given of their nests and eggs.

Forty common birds of West Virginia, E. A. BROOKS (*In Arbor and Bird Day Manual, Charleston, W. Va.: Dept. Free Schools, 1915, pp. 21-79, pls. 2, figs. 39*).—This paper gives popular accounts of 40 birds that occur commonly in West Virginia, including their range, habits, usefulness, song, etc.

Some Pennsylvania birds and their economic value, H. A. SURFACE (*Bi-Mo. Zool. Bul. Penn. Dept. Agr., 3 (1913), No. 5-6, pp. 153-216, pls. 11*).—This bulletin, which deals chiefly with the families including the larks, crows, and sparrows, is based upon the results of investigations by the author and by the Bureau of Biological Survey of this Department.

The practical value of birds, J. HENDERSON (*Univ. Colo. Bul., 13 (1913), No. 4, pp. 48*).—A discussion of the economic importance of birds, based upon a very extensive review of the literature, 208 references to which appear as footnotes to the text. A bibliography of 7 pages is appended.

Some observations on the food of nestling sparrows, W. E. COLLINGE (*Jour. Bd. Agr. [London], 21 (1914), No. 7, pp. 618-623*).—This is a report of work carried on in continuation of that previously noted (*E. S. R., 28, p. 450*).

During 1913 and 1914 over 280 specimens were examined, 200 having been obtained in fruit-growing districts and 87 from suburban districts. The results of the examinations of the stomach contents are presented in tabular form.

"In a single day 100 nestling house sparrows require nearly 2,000 insects for food in fruit-growing districts and about a third of that quantity in suburban districts. Excepting for a few spiders and earthworms, the whole of the food consists of injurious insects." As regards the house or English sparrow, the author finds that it is extremely difficult to arrive at any satisfactory and convincing conclusion as to its precise economic status. After carefully considering the results obtained from an examination of the stomach contents of 404 adult birds and of 329 nestling birds and also from an examination of the feces, he is of the opinion that if it were considerably reduced in numbers the good that it would do would probably more than compensate for the harm, especially in fruit-growing districts.

Comparative physiology and morphology of the arachnids, I. F. DAHL (*Vergleichende Physiologie und Morphologie der Spinnentiere unter Besonderer Berücksichtigung der Lebensweise. Jena: Gustav Fischer, 1913, pp. VI+114, figs. 223*).—This first part deals with the classification of the arachnids, their anatomy, color, etc.

Bibliography of Canadian entomology for the year 1913, C. J. S. BETHUNE (*Proc. and Trans. Roy. Soc. Canada, 3. ser., 8 (1914), Sect. IV, pp. 53-68*).—An annotated list of 136 titles, with a subject index.

Guide to California insects, C. W. WOODWORTH (*Berkeley, Cal.: The Law Press, 1913, pp. V+360, figs. 361*).—In the introduction to this work the author presents a brief account of the structure and classification of insects. The main part consists of systematic annotated lists of the insects known to occur in California. An appendix treats briefly of the collection, rearing, etc., of insects.

First biennial report of the Montana State Board of Entomology, R. A. COOLEY (*Bien. Rpt. Mont. State Bd. Ent., 1 (1913-14), pp. 50*).—This is the first report of the secretary of the newly created board of entomology. The regulations of the board are first presented. A report of the work of the Bureau of Entomology against spotted fever tick in cooperation with the board

is given by W. V. King (pp. 16-27); a review of Rocky Mountain spotted fever eradication work conducted by the U. S. Public Health Service in the Bitter Root Valley, Montana, is presented by L. D. Frieks (pp. 28-31); and a summary of a Report to the Montana State Board of Entomology Concerning Fly Investigations Conducted in the Yellowstone Valley During the Summer of 1914, is given by R. R. Parker (pp. 35-50).

Report of the entomologist, R. H. VAN ZWALUWENBURG (*Porto Rico Sta. Rpt. 1914, pp. 31-35*).—The author briefly reports on the occurrence of insects in Porto Rico from October 16, 1913.

The principal work of the past year has been with enemies of coffee and coffee shade trees, including the coffee leaf miner (*Leucoptera coffeella*); a shot-hole borer, *Xyleborus* sp., which works in guamá and guava; an undetermined pink coccus, attended by *Myrmelachista ambigua ramulorum* on the branches of guamá; and a flannel moth, *Megalopyge krugii*, abundant on guamá. The coffee leaf miner is said to be parasitized by two chalcidids, *Chrysocharis livida* and *Zagrammosoma multilineata*. *M. krugii* is very commonly parasitized by *Chalcis ovata* and an undetermined tachinid. *Micrococcus nigrofasciens*, the cause of a disease of May beetles, is said to be native to Porto Rican soils and apparently widespread. A brown "woolly bear" caterpillar, *Epantheria eridanus*, was fairly common on orange trees in the Mayaguez district. The small sweet potato weevil (*Euscepes (Cryptorhynchus) batatae*) made its appearance in the station planting during the winter months. Silk oak trees (*Grevillea robusta*) are sometimes severely attacked by the fringed scale (*Asterolecanium pustulans*).

Tenth annual report of the state entomologist and plant pathologist for 1914, G. M. BENTLEY (*Ann. Rpt. State Ent. and Plant Path. Tenn., 10 (1914), pp. 92, figs. 28*).—This is the usual annual report upon nursery inspection and other work (E. S. R., 31, p. 248). Two species of strawberry-root lice (*Aphis forbesi* and *Macrosiphum fragariae*) have been found to be destructive in Tennessee, one or the other having been found in 25 of the 96 counties of the State. Descriptive and biological notes are given of the two pests.

Injurious insects and other animals observed in Ireland during the year 1913, G. H. CARPENTER (*Econ. Proc. Roy. Dublin Soc., 2 (1914), No. 9, pp. 142-160, pl. 1, figs. 8*).—This, the author's usual annual report (E. S. R., 29, p. 555), deals briefly with the occurrence of the more important insect pests in Ireland during the year. Among those mentioned are the frit fly (*Oscinis frit*), the migratory apple aphid (*Aphis fitchii*), the giant willow aphid (*Lachnus viminalis*), the ox warble (*Hypoderma bovis*), etc. The author records the extraction of a fourth stage or mature larva of *H. bovis* from the back of a horse.

[Reports of the entomologist of Southern Rhodesia], R. W. JACK (*Rpt. Div. Agr. South. Rhodesia, 1911, pp. 46-53; 1912, pp. 50-55; 1913, pp. 43-47*).—These annual reports deal with the occurrence of and work with the more important insect pests in Southern Rhodesia.

[Insect pests in Mauritius], D. d'EMMEREZ DE CHARMOY (In *Summary of Investigations Made During the Period July 1 to November 30, 1914. Mauritius: Dept. Agr., 1914, pp. 3, 4*).—This report for the period following that previously noted (E. S. R., 32, p. 449) presents brief notes on the insects of special importance.

The pink sugar-cane borer (*Sesamia nonagrioides*) is said to show remarkable partiality to maize in the deposition of its egg; thus the larvæ may be readily destroyed upon a large scale by the use of maize as a trap crop. The eggs of this pest are said to be parasitized by *Ceraphron beneficiens*. The artichoke moth (*Porbe bjerckandrella*) was particularly prevalent during the period under

report. Particular attention was given to the life history of *Pulvinaria gaster-alpha*, which attacks cane, and to its parasite (*Aphycus* sp.). The pois sabre or jack-bean borer, which attacks both the plant itself and the pods, is said to have recently come to attention, it even causing the complete loss of a crop of the jack bean (*Canavalia ensiformis*) in the northern part of the island.

Insect notes (*Ann. Rpt. Agr. and Crown Lands Seychelles, 1913, pp. 13-17*).—Among the insect pests noted as of particular importance in Seychelles during the year are the green scale (*Lecanium viride*) on coffee, citrus, and ixora in spite of the fungus parasite *Cephalosporium lecanii*; the barnacle scale (*Aspidiotus ficus*) on coconut, frangipane (*Plumeria acuminata*), breadfruit (*Artocarpus incisa*), pseudo sago palm (*Cycas officinalis*), citrus, and roses; *L. hesperidum* on frangipane trees and water hyacinth (*Eichornia crassipes*); and *L. tessellatum* on coconut, takamaka (*Culophyllum inophyllum*), cinnamon, and water hyacinth, which was found during the year to be attacked by *C. lecanii*. It is stated that scales are always attended by ants, the commonest of which is *Tecchnomyrmex albipes*. A list is given of 12 coccids which ants attend and of 7 which they do not attend in the same degree. The coconut beetle (*Melittomma insulare*) is said to be kept under control better than formerly through the destruction of fallen trees and by removing the larvæ from standing trees.

Insect pests of field crops, L. HASEMAN (*Missouri Sta. Bul. 134 (1915), pp. 3-39, figs. 39*).—Popular accounts are given of the more important insect enemies of field crops in Missouri and means for their control.

Insect enemies of lucern, F. PICARD (*Prog. Agr. et Vit. (Ed. l'Est-Centre), 35 (1914), No. 18, pp. 555-561, pl. 1; abs. in Rev. Appl. Ent., 2 (1914), Ser. A, No. 10, pp. 577, 578*).—A brief account of the more important enemies of alfalfa in France, including *Phytonomus variabilis*, *P. nigrirostris*, *P. punctatus*, *Apion pisi*, *A. trifolii*, *Colaspidema atra*, *Lasia globosa*, *Colias edusa*, *C. hyale*, and *Agromyza nigripes*. A colored plate illustrating the pests is included.

Injury by tipulids and tabanids in the rice fields of Molinella, Bologna, G. DEL GUERCIO (*Redia, 9 (1913), No. 2, pp. 299-345, figs. 15; abs. in Rev. Appl. Ent., 2 (1914), Ser. B, No. 11, p. 167*).—This paper deals with the biology, occurrence, and injury of tipulids (*Tipula oleracea*) and tabanids (*Tabanus ignotus*) in Italian rice fields.

Protecting cabbage and cauliflower from attacks by worms, E. S. TUCKER (*Louisiana Stas. Bul. 154 (1915), pp. 16, figs. 2*).—This bulletin gives directions as to the manner in which the chewing insect enemies of these cruciferous plants can be successfully combated.

The cochylis, eudemis, and pyralid moths and altisa beetle of the vine, I. V. CLARIÓ-SOULÁN (*Cochylis, Eudemis, Piral y Altisa de la Vid. Barcelona: Consejo Prov. Fomento, 1913, pp. 68, pls. 4*).—This work deals with the biology and control of *Cochylis ambiguella*, *Eudemis botrana*, *Pyralis vitana*, and *Altica ampelophaga*.

[Insect pests of coconuts and cacao] (*Agr. News [Barbados], 14 (1915), Nos. 333, pp. 42, 43; 334, pp. 58, 59*).—A summary of data on the subject by Copeland (E. S. R., 32, p. 339) and by van Hall (E. S. R., 32, p. 745).

Summary of two years' study of insects in relation to pellagra, A. H. JENNINGS (*Jour. Parasitology, 1 (1914), No. 1, pp. 10-21*).—The conclusions drawn are similar to those by Jennings and King in the article previously noted (E. S. R., 29, p. 756).

Spraying for apple sucker and leaf-curling plum aphid, F. R. PETHERBRIDGE (*Jour. Bd. Agr. [London], 21 (1915), No. 10, pp. 915-919, pl. 1*).—The author reports control experiments with *Psylla mali* and *Aphis pruni* which led him to conclude that lime-salt and sulphur wash, applied as late as possible

previous to the hatching of the apple suckers, will control this pest and the leaf-curling plum aphid.

Effect of cyanid of potassium on trees, C. H. SHATTUCK (*Science, n. ser.*, 41 (1915), No. 1052, p. 324).—In continuing the discussion of this subject (E. S. R., 32, p. 754) the author states that his experience with cyanid of potassium, especially on elms and black locusts, has convinced him that it is a valuable remedy. He states that he has used potassium cyanid for several years in eliminating borers from various trees without causing any staining, killing, or in any way injuring the trees. He has prescribed it for the use of others for about 12 years in connection with forestry work and states that he has saved the lives of thousands of trees that have been attacked by boring and girdling insects. "Large groves of thrifty elms and black locusts in Kansas and other parts of the West have been completely rescued from the attacks of boring and girdling insects by means of cyanid of potassium."

New fumigating machines, G. P. GRAY (*Mo. Bul. Com. Hort. Cal.*, 4 (1915), No. 2, pp. 68-80, figs. 4).—Newly invented fumigating machines in which hydrocyanic gas is generated outside and conducted into the tents through hose are described and illustrated and the advantages and disadvantages discussed. The author concludes "that the machines are correct in principle, although there are still some points that need more thorough investigation. There are mechanical imperfections in the machines, but they nevertheless offer many important advantages over the pot system of dosage."

Cyanid fumigation of ships, N. ROBERTS (*Pub. Health Rpts. [U. S.]*, 29 (1914), No. 50, pp. 3321-3325).—This is a description of the method used at New Orleans.

On certain peculiar fungus parasites of living insects, R. THAXTER (*Bot. Gaz.*, 58 (1914), No. 3, pp. 235-253, pls. 4).—This paper gives descriptions of 5 genera and 10 species. Of the genera, 3 are very closely allied to well-known genera of Hyphomycetes, one belongs to the Hyphomycetes but is not closely related to any described species, and the other seems to be more nearly related to the Chytridiales than to other known organisms.

An outline of the subfamilies and higher groups of the insect order Thysanoptera, J. D. HOOD (*Proc. Biol. Soc. Wash.*, 28 (1915), pp. 53-60).—The author calls attention to the fact that within the last several years the number of known genera of Thysanoptera has increased from 45 to 169 and the known species from 175 to 795. With the increase in the size and importance of the group has come the necessity for a more comprehensive classification than that of Uzel proposed in 1895 (E. S. R., 8, p. 69).

The grape leafhopper, D. E. MERRILL (*New Mexico Sta. Bul.* 94 (1915), pp. 33, figs. 10).—This account relates to *Typhlocyba comes* and its variety *coloradensis*, which pest is a source of serious loss in yield each year in New Mexico. In addition to the loss in yield, it greatly lessens the vigor of the vines and sometimes they are even killed by it. There are two full broods and a small third each year in New Mexico. Control has been demonstrated to be possible and practicable by means of cultural methods, by spraying the spring brood of nymphs with kerosene emulsion or tobacco extracts, and by capturing the overwintering adults before they lay the eggs in the spring with traps.

Life-history studies of this insect by Quayle in California (E. S. R., 20, p. 557), by Hartzell in New York (E. S. R., 28, p. 855), and by Johnson in Pennsylvania (E. S. R., 30, p. 547) have been previously noted.

Psylla piri and the fight against it by means of a new combined kerosene-lime emulsion, GUDKOV (*Turkest. Selsk. Khoz.*, No. 3 (1914), pp. 263-289; *abs. in Rev. Appl. Ent.*, 2 (1914), Ser. A, No. 7, pp. 422, 423).—The author reports

observations made during the course of an outbreak of *P. piri* in Tashkend in 1913.

Kerosene-lime emulsion is said to have given the best results, both the immature stages and adults being killed by it. This emulsion is made by slaking 1 lb. of lime in $1\frac{1}{2}$ pints of water, and adding 1 lb. of kerosene, with constant agitation. It is stated that the amount of kerosene in the formula may be doubled when the application is to be made to mature leaves.

Spraying for the control of the walnut aphid, A. R. TYLOR (*California Sta. Circ.* 131 (1915), pp. 11, figs. 2).—This paper relates to *Chromaphis juglandicola*, a detailed account of studies of the life history and habits of which, by Davidson, has been previously noted (E. S. R., 31, p. 753).

During years of heavy infestation, which occasionally occur, the size of the European walnut is considerably reduced. The drain upon the tree is said to be heavy as a result of its attack, and the infestation may also increase the dissemination of the walnut blight.

The most effective spray for the control of the walnut aphid during the winter consists of commercial lime-sulphur, 5 gal.; unslaked lime, 25 lbs.; and water, 95 gal., at a cost of about \$2.55 per 200 gal. of spray. The spray should be applied before growth starts in the spring, an average of 25 gal. of spray being required for 10-year-old trees and 40 gal. for larger trees. The spray found most efficient for summer control consists of blackleaf 40, 1 pint; whale-oil soap, 4 lbs.; and water, 200 gal., at a cost of \$1.80 per 200 gal. of spray, when the materials are purchased in small amounts. About 30 to 35 gal. are required to cover 10-year-old trees. It is stated that the M. A. C. nozzles (E. S. R., 26, p. 49) are the most suitable ones found for spraying walnut trees.

The host plants of *Aphis rumicis*, J. DAVIDSON (*Ztschr. Wiss. Insektenbiol.*, 10 (1914), No. 5, pp. 189-190; *abs. in Rev. Appl. Ent.*, 2 (1914), Ser. A, No. 8, p. 494).—Substantially noted from another source (E. S. R., 32, p. 849).

Preliminary report on spraying of eggs for the control of the purple and green apple aphids of California, P. R. JONES (*Mo. Bul. Com. Hort. Cal.*, 4 (1915), No. 1, pp. 20-30).—"As far as can be determined at present under western conditions it is believed that dormant treatment for the eggs of the apple and purple aphids should be either commercial crude-oil emulsion 1:9 or 1:10 (where the concentrate contains about 85 per cent crude oil); home-made crude-oil emulsion from 10 to 15 per cent strength made from a crude oil running 19 to 23° B.; commercial lime-sulphur at 1:6 or 1:7, and the application made as late in the winter as possible before the buds start to show green.

"If homemade distillate-oil emulsions are used they should be made from heavy distillate, and the dilution in the tank figured to run 7 or 8 per cent oil."

Notes on the life history and habits of the rose scale, *Aulacaspis rosæ*, S. NAKAYAMA (*Jour. Ent. and Zool.*, 7 (1915), No. 1, pp. 45-54, figs. 25).—This paper is based upon observations made in the vicinity of Stanford University from December, 1912, to April, 1914. Studies of this scale, a common pest of blackberries, raspberries, and roses, by Smith, of New Jersey Experiment Station, have been previously noted (E. S. R., 14, p. 372), but observations of its biology on the Pacific coast have not previously been reported.

The author treats of the egg and its oviposition, the method of hatching, the larval stages, seasonal history, and natural enemies. The natural enemies noted include two lady beetles (*Chilocorus bivulnerus* and *Scymnus marginicollis*) and an undetermined hymenopterous parasite. A bibliography of 9 titles is included.

The San José and oyster-shell scales, L. CAESAR (*Ontario Dept. Agr. Bul.* 219 (1914), pp. 30, figs. 16).—A summarized account of the life history and habits, natural enemies, means of control, etc., of the San José scale (pp. 1-25) and of the oyster-shell scale (pp. 26-30) in Ontario.

The San José scale was introduced into Ontario by or before 1894 in shipments of infested nursery stock. There is believed to be no scale in the Province at present north of a line drawn from about Sarnia to Toronto and more than half of the territory south of this line is still free. It is thought that the scale will probably live and thrive wherever peaches will live and bear some fruit, even though not in a commercial way. The first brood of young scales begins to appear about June 20, and there are probably three or nearly three full broods a year in Ontario. While there are a number of native enemies that attack it in Ontario, up to the present time they have been of but little importance. The scale can be readily controlled by a single spraying once a year before the buds have burst in the spring. Badly infested trees should be sprayed twice the first year. A map is given showing the present distribution of the scale in Ontario.

The oyster-shell scale is said to occur in most of the orchards in every fruit district in Ontario.

The citricola scale, H. J. QUAYLE (*California Sta. Bul.* 255 (1915), pp. 405-421, figs. 7).—The citricola scale (*Coccus citricola*), first described as representing a new species by Campbell in 1914 (*E. S. R.*, 32, p. 57), is one of the most injurious scales attacking citrus trees in California. It not only necessitates the washing of the fruit because of the sooty mold fungus but seriously impairs the vigor of the tree and thereby greatly reduces fruit production. It is stated that in some groves the crop was reduced during the past year to the extent of 50 or 75 per cent as a result of its attack.

The scale was first found in the vicinity of Claremont in 1909 and at about the same time near Riverside and in certain sections of San Bernardino County. It has been known in the citrus sections of Tulare County for the past three or four years. In the countries south of the Tehachapi the citricola scale is found in Los Angeles, Orange, Riverside, and San Bernardino.

A brief account is given of its life history and habits, and a more technical paper is said to be in preparation. The young appear by the last week in April and continue to appear until August. During the summer, fall, and winter, the scales are found on the leaves almost exclusively and grow very slowly. In November and later a few migrate back to the twigs but the greatest migration occurs in March. With the warm weather of spring they rapidly mature and begin to deposit eggs late in April. Thus one full year is usually required for the life cycle.

While the parasites attacking this scale are common they never occur in large numbers. Those reared from it include *Coccophagus flavoscutellum*, *Aphycus flavus*, *C. lunulatus*, and *C. lecanii*. The lady beetle *Chilocorus bivulnerus* has been observed to feed upon this scale.

As regards remedial measures it is stated that fumigation between July 15 and September 15 is the most satisfactory treatment. When applied later the results of fumigation are less certain. Where fumigation is not feasible spraying may be employed.

The efficiency of fungoid parasites of scale insects (*Agr. News [Barbados]*, 14 (1915), No. 337, p. 110).—A brief review of the subject, particularly as relates to the West Indies.

The poison glands of the larva of the brown-tail moth (*Euproctis chrysoorrhoea*), CORNELIA F. KEPHART (*Jour. Parasitology*, 1 (1914), No. 2, pp. 95-103,

figs. 4).—The author here reports upon studies which have led her to confirm the finding of Tyzzer (E. S. R., 22, p. 55) that a definite poisonous principle is contained in the short barbed hairs of the larva of the brown-tail moth. "This substance is secreted by certain specialized hypodermal cells and is liberated in the blood through the sharp basal point of the hairs when they come in contact with the human skin. The poison glands are larger and fewer in number than the cells which form the hairs, there being one poison cell for each papilla on the tubercle instead of one for each hair."

Life history of the codling moth in Maine, E. H. SIEGLER and F. L. SIMAN-TON (*U. S. Dept. Agr. Bul. 252 (1915), pp. 50, pls. 2, figs. 9*).—The studies here reported, which form part of an investigation of the codling moth carried on by the Bureau of Entomology of this Department throughout the United States (E. S. R., 33, p. 61), are based upon work at Winthrop, Me., during the seasons of 1913 and 1914. It is stated that the methods of study have been essentially the same for the several States where the work has been undertaken.

The seasonal history studies of 1913 are first reported in detail (pp. 3-28), followed by those of 1914 (p. 28-46). A comparison of the life history of the codling moth during the two seasons, including a diagram of the seasonal history, follows. Much of the data is presented in tabular form.

It was found that in Maine the codling moth has one full generation, a very small percentage (1 to 2 per cent) of the individuals of which transforms to make a partial second generation. Pupation of the overwintering larvæ commences about the middle of May and extends to the first part of July. The length of the spring-brood pupal stage was found to average 21 days. Moths of the spring brood commence to emerge about two weeks after the petals have fallen and continue to issue for a period of about a month. The average time from the date of the emergence of the moths to the first oviposition was about four days. The oviposition of the spring-brood moths averaged 14 days. The average length of life of males of the spring brood was about 12 days, and of the females of the spring brood about 13 days.

"The earliest first-brood eggs were deposited approximately three weeks after the petals dropped. The incubation period of the first-brood eggs averaged eight days. The first-brood eggs began to hatch in from four to five weeks after the petals had fallen. The transforming larvæ of the first brood fed for a period of about 22 days. The overwintering larvæ of the first brood had an average feeding period of 28 days. The female larvæ of the first brood fed for a longer period than the male. The average time spent by the transforming larvæ in constructing their cocoons was about 6 days.

"Approximately from 1 to 2 per cent of the first-brood larvæ transformed to first-brood pupæ. The remainder of the larvæ did not transform until the following spring (spring pupæ). Pupation of the first or summer brood commenced during the latter part of July. The average length of the first-brood pupal stage was 15 days. The first or summer brood of moths began to emerge just previous to mid-August and continued to issue for a period of about one month. Oviposition by moths of the first brood began about mid-August. The life cycle of the first generation was 51 days. The complete life cycle was about 55 days.

"The average incubation period of the second brood of eggs was 11 days. The average feeding period of the second-brood larvæ was 46 days. The female larvæ of the second brood fed for a longer time than the male.

"The hymenopterous parasite *Ascogaster carpocapsæ* was frequently reared. The well-known beetle enemy *Tenebrioides corticalis* was commonly found attacking codling moth larvæ.

"The codling moth in Maine may be controlled with one spray thoroughly applied as soon as the petals drop. Arsenate of lead, paste 2 lbs. or powder 1 lb., to each 50 gal. of water, is recommended."

The sugar cane bud moth (*Loxostoma* sp.), E. JARVIS (*Queensland Agr. Jour.*, n. ser., 3 (1915), No. 2, pp. 72-76, fig. 1).—The Australian sugar cane bud moth (*Loxostoma* sp.), although usually of little economic importance, occasionally proves injurious to seed cane, sometimes as high as 80 per cent of the eyes in soft varieties being destroyed. It also feeds on the leaf sheath, gnaws the surface of the rind close to the buds, and often bores into the cane stalks, thus producing wounds that court disease through the invasion of fungi.

Technical descriptions are given of its several stages, together with a brief account of its habits, natural enemies, and control measures.

The grass moth (*Remigia repanda*), a pest of sugar cane, rice, and para-grass in British Guiana, G. E. BODKIN (*Jour. Bd. Agr. Brit. Guiana*, 7 (1914), No. 4, pp. 171-177).—This moth, *R. repanda* (*latipes*), has been a well-known pest for many years in British Guiana, although this is the first published account of its life history, habits, etc. It may be found throughout the year on sugar cane, rice, para grass, and other grasses throughout the coast lands of the colony. There are certain periods, particularly on the occurrence of rain after a prolonged drought, when it appears in vast hordes, completely destroying whole areas of these crops. It also occurs in several of the interior districts. It recently occurred as a serious pest in Trinidad and is also known as a pest in Jamaica. These are the only available records of the occurrence of the pest in the West Indies and elsewhere.

Technical descriptions of the larval stages of this moth which have been published by H. G. Dyar^a are included.

Flies in relation to disease.—Bloodsucking flies, E. HINDLE (*Cambridge, England: University Press, 1914*, pp. XV+398, figs. 88).—This volume, with the companion work by Graham-Smith on Nonbloodsucking Flies (E. S. R., 30, p. 552), covers the general subject of flies in their relation to disease. The author's object in preparing the book has been to collocate the more important observations concerning the part taken by biting flies in the transmission of disease. In doing this he has included notes on and tables for the separation of the flies, mosquitoes, etc., concerned and descriptions of the infections transmitted, but no account of the clinical symptoms of the various diseases has been attempted. Particular attention has been given to the life history and bionomics of the more important forms mentioned, to the manner in which the infection is conveyed, and to preventive measures.

After a short introduction follow chapters on the structure and classification of the Diptera, accompanied by a list of biting flies known to transmit any infection. Each family, including any such carriers of disease, is then dealt with separately and in most cases some important member of the family is described in greater detail. Usually the description of the infections immediately follows that of the family concerned in their transmission.

Two extensive lists are included, the one above mentioned giving species of Diptera supposed to convey infective agents, the other tabulating 241 species of known anophelines, their synonymy, and relation to malaria. References to the literature are given at the end of many of the chapters. In preparing the work the author has covered the literature on the subject up to the beginning of 1913.

Dr. A. F. A. King on mosquitoes and malaria, L. O. HOWARD (*Science*, n. ser., 41 (1915), No. 1052, pp. 312-315).—The author reviews the writings and

^a Proc. U. S. Nat. Mus., 23 (1901), pp. 276-280.

views of Dr. King in 1881, 1882, and 1883 in which he presented reasons why malaria would be found to be transmitted by mosquitoes.

The biology of the North American crane flies (Tipulidæ).—III, The genus *Ula*, C. P. ALEXANDER (*Jour. Ent. and Zool.*, 7 (1915), No. 1, pp. 1-9, figs. 8).—In continuation of the article previously noted (E. S. R., 32, p. 153) the author deals with the genus *Ula* and *U. elegans*.

Notes on the life history and anatomy of *Siphona plusiæ*, W. BLOESER (*Ann. Ent. Soc. Amer.*, 7 (1914), No. 4, pp. 301-309, figs. 10).—This article relates to a tachinid, *S. plusiæ*, described by Coquillett in 1897 as bred from a cutworm, and now found by the author to be a parasitic in the larvæ of *Phryganidia californica* taken from oak trees at Palo Alta, Cal.

The house fly (*Musca domestica*), its structure, habits, development, relation to disease, and control, C. G. HEWITT (*Cambridge, England: University Press, 1914*, pp. XV+382, pls. 3, figs. 101).—This work consists of six parts which deal with the subject as follows: (1) The structure and habits of the house fly (pp. 1-86); (2) the breeding habits, life history, and structure of the larvæ (pp. 87-150); (3) the natural enemies and parasites of the house fly (pp. 151-185); (4) other species of flies frequenting houses (pp. 186-217); (5) the relation of house flies to disease (pp. 218-316; and (6) control measures (pp. 317-335).

In the preparation of the work the author endeavored to review the entire literature relating to this insect. It is not intended as a popular treatise on the subject, but primarily for the use of entomologists, medical men, health officers, and those similarly engaged or interested in the subject. A 36-page bibliography is appended and author and subject indexes are included.

A popular handbook on this subject by the author has been previously noted (E. S. R., 28, p. 560), as have several papers reporting investigations upon which this work is based in part (E. S. R., 24, p. 356; 31, p. 455).

Observations on the feeding habits of the stable fly, *Stomoxys calcitrans*, C. G. HEWITT (*Proc. and Trans. Roy. Soc. Canada*, 3, ser., 8 (1914), Sect. IV, pp. 37-42, pl. 1).—The author deals with this subject under the headings of method of feeding, period of digestion, examination of fecal deposits, and frequency of feeding.

The author reports that he was unable, except in one case, to induce the flies selected for the purpose to take their first feed for at least 24 hours, although they were repeatedly placed on the skin. They usually fed readily between 24 and 48 hours after emergence. Records show that the average length of time occupied in feeding, based upon 22 engorgements, was 8.9 minutes when undisturbed. A summary of the results of feeding experiments conducted are presented in tabular form.

Cherry fruit flies, L. CAESAR and G. J. SPENCER (*Ontario Dept. Agr. Bul.* 227 (1915), pp. 30, figs. 18).—Two species of cherry fruit flies, namely, *Rhagoletis cingulata* and *R. fausta*, for which the names white-banded cherry fruit fly and black-bodied cherry fruit fly, respectively, are proposed, are said to cause much loss to cherry growers in Ontario. The insects are distributed here and there all over the Niagara district and probably in many of the other cherry districts of the Province. The percentage of wormy cherries in infested orchards varies from 5 to 99, many otherwise good orchards sometimes being so badly infested that the fruit can not be picked. Varieties like Early Richmond and early sweet cherries are almost exempt from attack, but all later sour and sweet cherries are infested, especially Montmorency and Morello. So far as known no other orchard fruit is subject to injury from the pest.

The black-bodied cherry fruit fly appears on the trees about a week earlier in the spring than the white-banded cherry fruit fly. In Niagara the former

may usually be seen about the end of the first week in June, the latter about June 11. The adults are thought to live on an average about three weeks. Oviposition commences ten or twelve days after the adults emerge, the eggs being deposited just under the skin of the cherries. They hatch in about five days and the maggots become full grown in about 14 days. On leaving the fruit the larvæ work into the soil about an inch or go down cracks, if the surface is hard, and soon change to the puparia. They then remain dormant until the next June, when they change to flies and move about through the orchard.

Experiments in 1913 and 1914, both on large orchards and on caged trees, show that the insects can be easily and cheaply controlled by poisoning the adults before they can lay their eggs. "The best mixture to use is from 2 to 3 lbs. arsenate of lead (paste) to 40 gal. of water, sweetened with 1 gal., or nearly 1 gal., of cheap molasses (black strap). Arsenate of lead without the molasses will probably give almost as good results. Until the pest is nearly annihilated two applications should be given each year in badly infested orchards, the first about June 8, or about a week before Early Richmonds begin to ripen, the second application ordinarily about June 20, or about the time the Montmorcencies are showing the first symptoms of the red blush. It is well to spray plum, apple, and pear trees that happen to be among or very close to the cherry trees, as the flies rest and feed on their foliage also. Early varieties of cherries should not be given the second application, as they are then too near picking time.

"Two years' treatment should free an orchard of the pest, unless fresh infestation comes from outside sources. . . . The cost of spraying trees 14 years of age twice should not be more than 5 cts. per tree. This includes cost of mixture, labor, and horse. . . . Close observations for two years in five orchards, along with some special tests, show that bees are not attracted to the poison, and that there is no danger of poisoning them if the directions given above are followed."

A bulletin by Illingworth reporting studies of these pests in New York has been previously noted (E. S. R., 29, p. 55).

The ravages, life history, weights of stages, natural enemies, and methods of control of the melon fly (*Dacus cucurbitæ*), H. H. P. and H. C. SEVERIN and W. J. HARTUNG (*Ann. Ent. Soc. Amer.*, 7 (1914), No. 3, pp. 177-212, figs. 57).—A report of studies based upon observations in Hawaii in which the authors consider the native home, field observations in a pumpkin patch, food plants, life history, natural enemies, methods of control, etc. A report of studies of this pest by Back and Pemberton has been previously noted (E. S. R., 32, p. 452).

A bibliography of 11 titles is appended.

The progress of *Scymnus bipunctatus*, H. S. SMITH (*Mo. Bul. Com. Hort. Cal.*, 3 (1914), No. 12, p. 535, fig. 1).—A colony of several thousand adults of this lady beetle, reared from specimens obtained in the Philippines by the author in the fall of 1913 and liberated in June, 1914, at Alhambra, is said to have been found breeding by thousands on lemon trees. It is expected that it will be of considerable value in controlling the citrus mealy bug (*Pseudococcus citri*).

Some notes on life history of lady beetles, MIRIAM A. PALMER (*Ann. Ent. Soc. Amer.*, 7 (1914), No. 3, pp. 213-238, pls. 2).—Biological notes are here presented on the more common coccinellids found in Colorado, namely, *Hippodamia convergens*, *Coccinella 5-notata*, *C. monticola*, *C. 9-notata*, *Adalia melanopleura*, *A. unnectans*, *A. coloradensis*, *A. humeralis*, *Olla abdominalis*, *H. sinuata*, *H. parenthesis*, *C. sanguinea*, and *Scymnus* sp. Special attention is paid to the

duration of the life cycle and the habits regarding egg laying and feeding, with incidental observations on injurious influences and other points. Descriptions are given of the beetles in all stages, which are also illustrated in color.

The violet rove beetle, F. H. CHITTENDEN (*U. S. Dept. Agr. Bul. 264 (1915), pp. 4, fig. 1*).—*Apocellus sphaericollis*, known as the violet rove beetle, has been reported from time to time since 1901 as an enemy to violets and other succulent ornamental plants in the District of Columbia and at St. Louis, Mo. The injury is caused by its feeding on the flowers and leaves. Since the beetle lives normally, like others of its kind, on old dead leaves or in soil covered by leaves over winter, the use of decaying leaves deposited in piles at regular intervals about infested plants will serve as a trap for them, and they may be readily destroyed by dipping in hot water or otherwise. Sterilization of the leaves used as a mulch will bring about the destruction of the insect and prevent its introduction into the greenhouse or flower bed.

The small sweet potato weevil (*Cryptorhynchus batatae*), L. A. WHITNEY (*Mo. Bul. Com. Hort. Cal., 4 (1915), No. 3, pp. 162-164, figs. 5*).—While this pest has not become established in California it is said to have been taken in quarantine repeatedly; in some shipments inspected fully 50 per cent of the tubers examined had been riddled by the larvæ.

Recent studies of the Mexican cotton-boll weevil, B. R. COAD (*U. S. Dept. Agr. Bul. 231 (1915), pp. 34, fig. 1*).—This is a report of investigations conducted by the author in connection with and in continuation of those previously noted (*E. S. R., 31, p. 458*).

Among the more important observations noted are those relating to longevity of adult weevils, it having been found in an experiment during 1914 at Washington, D. C., that they may be kept in a dormant state for more than a year; reproduction, including the length of periods in the life of the adult weevil; rate of oviposition, etc.; incubation period of the egg; total developmental period; generations; important food adaptations, etc.

Bee keeping for profit, W. S. MORLEY (*London: Cassell & Company, Ltd., 1914, pp. 124, pls. 8*).—A popular handbook.

The orientation of ants and the orientation problem in general, R. BRUN (*Die Raumorientierung der Ameisen und das Orientierungsproblem im allgemeinen. Jena: Gustav Fischer, 1914, pp. VIII+234, figs. 51*).—A critical experimental study and a contribution to the mneme theory. A bibliography of 124 titles is included.

Chalcidids of the genus *Isosoma* injurious to grain crops in Russia, M. N. RIMSKY-KORSAKOV (*Trudy Bûro Ent. [St. Petersburg.], 10 (1914), No. 11, pp. 84, pls. 3, figs. 50; abs. in Rev. Appl. Ent., 2 (1914), Ser. A, No. 7, pp. 470-473*).—This is a report of investigations conducted in the Government of Kherson. Five species of *Isosoma* were found of which two are described as new. It is pointed out that but little is as yet known of the biology of members of this genus in Europe.

[Studies of the Siphonaptera or fleas], C. FOX (*Pub. Health Serv. U. S., Hyg. Lab. Bul. 97 (1914), pp. 31, pls. 22*).—Three papers are here presented. The first relates to Some New Siphonaptera (pp. 7-17); the second consists of A Further Report on the Identification of Some Siphonaptera from the Philippine Islands (p. 18); and the third takes up The Taxonomic Value of the Copulatory Organs of the Females in the Order Siphonaptera (pp. 19-22).

A synopsis of the British Siphonaptera, N. C. ROTHSCHILD (*Ent. Mo. Mag., 3. ser., 1 (1915), No. 3, pp. 49-112, pls. 8*).—The author recognizes 45 species of fleas representing 16 genera as occurring in Great Britain. The paper includes a synonymic catalogue of the species.

FOODS—HUMAN NUTRITION.

Composition of the grain, flour, and milling offals of four varieties of wheat, H. HUNTER (*Dept. Agr. and Tech. Instr., Ireland Jour.*, 15 (1915), No. 3, pp. 550-562).—Analytical data are reported regarding the composition of the grain, flour, and various milling by-products of Red Fife, Square Head Master, White Queen, and White Stand Up wheats. From the results obtained it is concluded that the differences in composition of these four wheats are the direct cause of differences in the flours and offals obtained in milling.

Durum wheat as a substitute for other varieties of grain in bread making, A. CASELLI (*Agr. Colon. [Italy]*, 9 (1915), No. 4-5, pp. 217-227).—Analyses and baking tests reported of flours made from durum wheat and other grains indicate that this variety of wheat is very satisfactory for bread making.

The chemical composition of some corn-meal products and the digestibility of protein, RAMMSTEDT (*Arch. Hyg.*, 81 (1913), No. 6, pp. 286-306; *abs. in Hyg. Rundschau*, 25 (1915), No. 3, p. 108).—The results of a number of analyses are reported comprising the chemical composition of corn, wheat, and rye flours. Values are also given for the digestibility of the protein content of flours prepared from peas, lentils, beans, corn, wheat, buckwheat, and rye, as determined by artificial digestion at from 38 to 40° C., for 24 hours, with a pepsin-hydrochloric acid solution.

The chemistry of rice polishings, H. FRASER and A. T. STANTON (*Lancet [London]*, 1915, I, No. 20, pp. 1021, 1022).—The experimental data previously reported (*E. S. R.*, 31, p. 555) are reviewed in the light of recent investigations by other workers.

On the nature of the sugars found in the tubers of sweet potatoes, K. MIYAKE (*Jour. Biol. Chem.*, 21 (1915), No. 2, pp. 503-506).—An analytical study of the nature of the sugars in the sweet potato is summarized as follows:

"Sugar of the sweet potato tubers is made up of both reducing and non-reducing sugar. The reducing sugar consists of both glucose and fructose, while the nonreducing sugar is sucrose. The presence of pentose, galactose, and mannose molecules is excluded. The presence of maltose is also excluded."

On the nuclein bases found in the shoots of *Aralia cordata*, K. MIYAKE (*Jour. Biol. Chem.*, 21 (1915), No. 2, pp. 507-509).—The results are reported of a study of the chemical nature of the nuclein bases found in the shoots of *Aralia cordata*. The presence of guanin and xanthin was detected; adenin and hypoxanthin were not found present.

Are the hardened fats suitable food for man? P. O. SÜSSMANN (*Arch. Hyg.*, 84 (1915), No. 2-3, pp. 121-145).—Results are reported of the analysis of a number of samples of hardened sesame, peanut, and cotton-seed oils, which were found to contain from 1 to 1.1 mg., 1.6 to 6.3 mg., and 0.07 to 0.4 mg. of nickel per kilogram of fat, respectively. Larger amounts of iron were detected, but these were regarded as having no hygienic significance.

In a series of feeding experiments with dogs as much as 0.75 per cent of the body weight of hardened fat was eaten daily without noticeable disturbances. The author concludes that the amount of nickel present in the hardened fat is too small to produce any ill effects, and that these fats are in every way suitable for human food.

Does butter fat contain nitrogen and phosphorus? T. B. OSBORNE and A. J. WAKEMAN (*Jour. Biol. Chem.*, 21 (1915), No. 1, pp. 91-94).—A more or less controversial article, which presents further analytical data in support of the contention that the growth-stimulating properties of butter fat are not due to the presence of nitrogen or phosphorus. Earlier work has been noted (*E. S. R.*, 33, p. 262).

Chemical composition of Hungarian flower honeys, S. WEISER (*Kísérlet. Közlem.*, 18 (1915), No. 2, pp. 365, 366).—Analytical data are given regarding a number of samples of honey made from several different flowers.

Molasses, A. MCGILL (*Lab. Inland Rev. Dept. Canada Bul.* 312 (1915), pp. 21).—Analytical data are given regarding 140 samples purchased in Canada as molasses. Of these, 75 contained less than 40 per cent of cane sugar, and are questioned by the author as to their suitability for food purposes. In his opinion they should be sold under the name of black strap rather than molasses. Thirty-eight samples contained more than 5 per cent of ash. The need for a legal standard for molasses is urged.

Economical electric cooking.—Competition of electricity with gas and coal requires conservation of heat energy and utilization of economical temperature, P. W. GUMAER (*Engin. Mag.*, 49 (1915), No. 4, pp. 580-583, figs. 6).—From the results of an extended series of experiments as to the economy of electric cooking the author gives the ranges of temperature at which the oven should be maintained for the most economical baking of bread and cakes and the roasting of meats.

Report of the Committee on Terminals and Transportation of the New York State Food Investigating Committee, W. C. BROWN, F. W. STEVENS, and G. M. TUCKER (*Albany: J. B. Lyon Company*, 1913, pp. 39).—A report of an investigation to determine the effect of railroad rates, railroad terminal facilities, and railroad service upon the cost of foodstuffs in New York City, Albany, Syracuse, and Buffalo during the past 10 years. One conclusion drawn from the data presented is that the tendency of railroad rates has been downward, and that they represent a very small part of the ultimate price of foodstuffs. A number of recommendations are made as to improvement in methods of freight distribution.

A statistical study of the relation of pellagra to use of certain foods and to location of domicile in six selected industrial communities, J. F. SILER, P. E. GARRISON, and W. J. MCNEAL (*Arch. Int. Med.*, 14 (1914), No. 3, pp. 293-373, figs. 29).—This statistical study was made in six cotton-mill villages in Spartanburg County, South Carolina. Records were obtained of the frequency of use of certain elements of diet and of the general sanitary condition of the houses, as well as information regarding the association with pellagra of the inhabitants. The following conclusions are drawn by the authors:

Pellagra spread from a preexisting case as a center in the six villages here studied. It was transmitted to new victims only through very short distances and chiefly to those immediately associated in the home with a preexisting case of the disease.

Frequent use of corn meal as an article of diet was not a factor in the causation of pellagra in these villages, and there was discovered no evidence that canned goods have anything to do with its causation. The frequent, even daily, use of fresh meat and of eggs afforded no relative protection. The daily use of milk seemed to diminish to some extent the danger of contracting pellagra in 1912 and 1913, although its use did not fully insure against the development of the disease.

Studies on the digestion of cooked meat in the case of dogs, E. ZUNZ (*Biochem. Jour.*, 9 (1915), No. 1, pp. 17-35).—In continuation of previous work (E. S. R., 32, p. 256), the author reports further analyses of the stomach contents of laboratory animals (dogs) after the ingestion of meat to determine the character of the protein decomposition products as an index to the protein metabolism.

Contribution to the knowledge of the utilization of vegetable protein by the animal organism, H. BORUTTAU (*Biochem. Ztschr.*, 69 (1915), No. 3-4, pp.

225-244).—Feeding experiments with laboratory animals (dogs) are described from which the author concludes that vegetable proteins are equal to animal proteins in supplying essential amino acids, provided the protein of the bran is rendered available and a sufficient variety of plant food is supplied.

The specific heat of muscle protein and its significance with regard to the heat of combustion, O. KRUMMACHER (*Ztschr. Biol.*, 65 (1915), No. 7-8, pp. 355-364).—The author reports a number of measurements of the specific heat of muscle protein from which it is deduced that its heat of combustion at 37° C. is 0.15 per cent greater than at 17°.

The digestion and absorption of protein and fat in normal and depancreatized animals, E. W. H. CRUICKSHANK (*Biochem. Jour.*, 9 (1915), No. 1, pp. 138-155).—In feeding experiments with laboratory animals (dogs) the absorption of nitrogen was studied in the case of normal animals given low and high protein and low and high fat diets. The variations from these results when the animal was partially depancreatized, totally depancreatized, and when raw pancreas was added to the diet were also determined.

The results obtained showed that the removal of the pancreas caused an immediate and serious disturbance of the digestion of both protein and fat.

The metabolism of creatin and creatinin.—VII, The fate of creatin when administered to man, V. C. MYERS and M. S. FINE (*Jour. Biol. Chem.*, 21 (1915), No. 2, pp. 377-381).—Two feeding experiments are described in which the authors served as subjects. Living on meat and meat extract free diets for 12 and 13 days, they ingested 1 gm. of creatin on the seventh day and increased the amount until on the eleventh day 5 gm. was taken. From the increased excretion of creatinin in the urine, it is concluded that the increase in the creatinin excretion actually comes from the administered creatin.

The metabolism of creatin and creatinin.—VIII, The presence of creatinin in muscle, V. C. MYERS and M. S. FINE (*Jour. Biol. Chem.*, 21 (1915), No. 2, pp. 383-387).—Results are reported of analyses to determine the creatinin content of fresh muscle from the rabbit, cat, and dog, and from human bodies. The authors conclude that these results strongly support the view held by others and themselves that the urinary creatinin originates chiefly in the muscle tissue.

The metabolism of creatin and creatinin.—IX, The creatin content of the muscle of rats fed on isolated proteins, V. C. MYERS and M. S. FINE (*Jour. Biol. Chem.*, 21 (1915), No. 2, pp. 389-393).—In this paper data are given showing the creatin content of the muscle of rats fed on isolated proteins (casein, edestin, and lactalbumin). The results indicate, in the opinion of the authors, that the creatin content of rat muscle varies within comparatively narrow limits, and that the concentration of muscle creatin is only slightly influenced by feeding proteins containing varying quantities of arginin.

Does the cholesterol of the diet exert an influence on the excretion of cholesterol in the bile? L. D'AMATO (*Biochem. Ztschr.*, 69 (1915), No. 3-4, pp. 217-224).—Feeding experiments are reported in which dogs having an artificial gallic fistula were maintained on a diet rich in lipid material. A constant, although very small, increase in bile cholesterol and bile salts was noted.

Bodily changes in pain, hunger, fear, and rage, W. B. CANNON (*New York and London: D. Appleton & Co., 1915, pp. XIII+311, figs. 39*).—This book brings together and discusses the results of recent investigations in this field of physiology. The chapters on the effect of the emotions on digestion and the nature of hunger are of special interest to students of nutrition.

A study of prolonged fasting, F. G. BENEDICT (*Carnegie Inst. Washington Pub. 203 (1915), pp. 416, pls. 7, figs. 46*).—This publication reports observations made upon a human subject who underwent a continuous fast for 31 days.

The subject of the experiment subsisted entirely without food, but ingested 750 cc. of water daily. In order to investigate completely the physiological and psychological conditions prevailing at intervals during the fasting period, measurements were made of body weight, body temperature, pulse rate, and blood pressure. These were supplemented by frequent blood tests and determinations of the mechanics of respiration by measuring the ventilation of the lungs, the alveolar air, and the respiration rate. In addition to these tests, records were kept of examinations of the urine, for the direct determination of nitrogen, acid and basic radicles, carbon, and energy. It was possible also to study the subject's mental attitude during the fast and to make psychological tests.

By means of the universal respiration apparatus was studied the influence of various factors upon the respiratory exchange, observations being made while the subject was at rest, while doing light work (writing), and while breathing air rich in oxygen. The metabolism was also studied by means of the respiration calorimeter, the subject sleeping each night in a body calorimeter.

The data are summarized to describe the nature and extent of the catabolism, including both material and energy losses from the body.

Basal metabolism and body surface—a contribution to the normal data, J. H. MEANS (*Jour. Biol. Chem.*, 21 (1915), No. 2, pp. 263-268, figs. 2).—Determinations are reported of the basal metabolism of 16 normal subjects, using the Benedict universal respiration apparatus. The surface area was also calculated by the formulas used by other investigators, and the accuracy of these formulas is discussed.

The water content and temperature of expired air, G. GALEOTTI (*Pflüger's Arch. Physiol.*, 160 (1914), No. 1-3, pp. 27-41, fig. 1).—This paper reports a study of the actual water content of expired air under normal conditions and as affected by the humidity and temperature of the environment. The temperature of the exhaled air was studied with regard to its humidity, the regularity of breathing, the influence of inhaling warm air, and the effect produced by a cold bath.

The temperature of the expired air was found to vary from 34.4° to 35.7° C. at a room temperature of from 16° to 25°. Both the temperature and the humidity of the environment influenced these factors in the expired air. The effect of the cold bath was to lower the temperature of the air. As a result of these observations the author concludes that the vasomotor condition of the lungs influences the temperature and consequently the water content of the expired air.

The temperature of expired air, G. GALEOTTI, V. SCAFFIDI, and O. BARKAN (*Arch. Ital. Biol.*, 62 (1914), No. 3, pp. 411-420).—Measurements are reported of the temperatures of the body and of the expired air under normal conditions, after fatigue, and under the influences of cold and cutaneous vaso-dilation.

At a room temperature of 10° C., that of the expired air was 33 to 34°. By increasing the temperature of the environment (16 to 25°) the temperature of the expired air was raised somewhat (34.4 to 35.7°). After fatigue this value remained within normal limits. These experiments are supplementary to those reviewed above.

Researches on the exchange of energy in live animal tissues.—I, Microcalorimetry applied to animal tissues, A. O. DEALMEIDA (*Amer. Jour. Physiol.*, 37 (1915), No. 3, pp. 505-514, figs. 2).—The author describes the technique and apparatus employed in experiments designed to measure the heat developed by animal tissue separated from the organism.

Investigations at the nutrition laboratory of the Carnegie Institution of Washington, Boston, Massachusetts, F. G. BENEDICT (*Science*, n. ser., 42

(1915), No. 1072, pp. 75-84, fig. 1).—In this address the author discusses various phases of the work of the laboratory and describes some of the apparatus used. The results of experiments, most of which have been noted from other sources, are briefly summarized.

ANIMAL PRODUCTION.

Foodstuffs for animals and their valuation, F. A. STOCKDALE (*Mauritius: Dept. Agr., 1915, pp. 5*).—Analyses are given of cane tops, manioc, sweet potatoes, wheat bran, rice bran, coconut meal, cotton-seed meal, and molasses.

Some facts about concentrated feeds, W. H. STROWD (*Wisconsin Sta. Bul. 253 (1915), pp. 60, fig. 1*).—Analyses are given of oil meal, cotton-seed meal, gluten feed, distillers' dried grains, hominy feed, bran, wheat, middlings, shorts, flour middlings, red dog flour, germ middlings, rye middlings, rye bran, barley shorts, buckwheat bran, dried brewers' grains, dried brewers' yeast, malt sprouts, alfalfa meal, tankage, blood meal, meat scrap, bone meal, tankage, molasses feed, corn, corn-soy bean silage, alfalfa hay, dried potato peelings, wet vinegar refuse, and various mixed and proprietary feeds.

Vine prunings as fodder, F. DE CASTIELLA (*Jour. Dept. Agr. Victoria, 13 (1915), No. 5, pp. 310-314*).—Successful experiments in feeding vine prunings to cattle, sheep, and horses are reported.

Silage feeding, C. I. BRAY (*Oklahoma Sta. Circ. 36 (1914), pp. 2-8*).—This circular gives general information on the feeding of silage to live stock.

The comparative values of cotton-seed, cotton-seed meal, and corn, as shown by chemical analyses, C. K. FRANCIS (*Oklahoma Sta. Circ. 37 (1914), pp. 4*).—Data as to the composition and digestible nutrients of raw cotton-seed and cotton-seed meal are given. Suggestive rations for beef cattle and dairy cows are included.

Coconut cake and palm-nut kernel cake (*Jour. Bd. Agr. [London], 21 (1915), No. 11, pp. 1025-1032*).—Data are summarized as to the average composition of coconut cake and palm-nut cake and digestibility coefficients, and a general résumé of experiments in feeding these products is included.

It is said that palm-nut kernel and coconut cakes or meals are valuable feeding stuffs, particularly for milch cows. They are also useful for replacing oats for horses, but are probably of less value for fattening steers, sheep, and pigs.

The feeding value of refuse brewers' yeast: Hungarian experiments, J. SCHANDL (*Köztelek [Budapest], 24 (1914), No. 76, pp. 2658, 2659; abs. in Internat. Inst. Agr. [Rome], Mo. Bul. Agr. Intcl. and Plant Diseases, 6 (1915), No. 2, pp. 276, 277*).—The composition of brewers' yeast is given as moisture 87.67 per cent; protein, 6.69; fat, 0.14; nitrogen-free extract, 4.49; and ash, 1.01.

It is said that the product can not be used for feeding purposes as it comes from the brewery, owing to the danger of abnormal or excessive fermentation in the stomach of the animal, and to its bitter taste and strong smell. After subjecting it to a simple cooking process it was readily accepted by sheep and pigs, but cows and horses refused to touch it until after 24 hours, when the disagreeable taste and smell had disappeared.

In an experiment in which two rams were fed 1.5 lbs. of chopped clover and 0.5 lb. of yeast the digestibility coefficients of the yeast were dry matter, 89 and 54 per cent; protein, 97 and 86 per cent; and nitrogen-free extract 82 and 86 per cent, respectively.

In experiments with five cows fed in three periods of 30 days each, as follows: First and third periods 4.4 lbs. of sunflower cake, second period 2.2 lbs. of sunflower cake and 11 lbs. of yeast, it was found that the yeast exerted no specific influence on the yield of milk.

It is said that the following quantities of the yeast per 1,000 lbs. live weight may safely be fed: Horses, 4 lbs.; cows, 10 lbs.; sheep, 5 lbs.; and pigs, 10 lbs.

The action of taka-dia-stase on the digestive power of the healthy animal, S. SAWAMURA (*Jour. Col. Agr. Imp. Univ. Tokyo*, 5 (1915), No. 3, pp. 271-281).—From feeding trials with a sheep it is concluded that the addition of 0.5 gm. of taka-dia-stase to a basal ration of hay, bran, and starch did not increase the digestibility of the starch, but that of crude fiber was slightly augmented. The quantity of digestible protein was practically the same as where the basal ration alone was fed, from which it is concluded that the addition of taka-dia-stase did not increase the secretion of digestive enzymes in the animal body.

In a second trial with two sheep in which 1 gm. of taka-dia-stase was added to the basal ration, the digestibility of the starch was increased, as was also that of the crude fiber and protein. The addition of the taka-dia-stase apparently slightly diminished the secretion of the digestive enzymes.

The results of these experiments indicate that the addition of a very small dose of a digestive enzyme to the feed of a healthy animal has no effect on the digestion, but that when taka-dia-stase is given in a quantity corresponding to the $\frac{1}{2000}$ part of the live weight the digestion of starch is somewhat augmented by it, and that of protein is also increased. However, as the increase of the digestibility of starch is very small, it is not deemed economical to use any digestive enzyme in the feeding of domestic animals.

A new method (Kjelleström) for the determination of the live weight of cattle, E. MASCHERONI (*Indus. Latt. e Zootec.*, 13 (1915), No. 7, pp. 100-102, fig. 1).—A method for the determination of the live weight of cattle is described, certain measurements of length and heart girth being used.

The cost of maintenance of cattle as influenced by condition, previous plane of nutrition, age, season of the year, length of time on maintenance, type, and size of animal, P. F. TROWBRIDGE, C. R. MOULTON, and L. D. HAIGH (*Missouri Sta. Research Bul.* 18 (1915), pp. 5-62, figs. 17).—These studies were made with 26 steers. A portion of the steers were selected as calves, full fed for four months, and assigned to lots. Lot 1 was full fed and crowded, lot 2 was fed for maximum growth without laying on appreciable fat, and lot 3 was fed for retarded growth, about $\frac{1}{2}$ lb. grain daily when yearlings. Collectively the three lots were known as the "use of food" group. Another portion of the steers belonged to a group known as the "regular-maintenance" group. A third group was called the "special-maintenance" group. They were full fed until 11 months old, when they were divided into three lots, one lot being held at maintenance, a second lot being allowed to gain $\frac{1}{2}$ lb. per day, and a third lot losing $\frac{1}{2}$ lb. per day.

Three other steers were full fed for several months. Then followed 30 days of submaintenance or loss of weight, and then maintenance for 60 days. One of these steers was then full fed for four months and nine days, put on maintenance for 240 days, again full fed for five months, and finally put on maintenance for 110 days. This trial ended one month before slaughtering. A second steer, after the above treatment, for three months was fed a maintenance ration plus one-half the productive feed above maintenance fed to the first steer, was then put on maintenance for 290 days, again fed as above for five months, and finally put on maintenance for 110 days. This trial ended about five months before slaughtering. The third steer, after the same preliminary treatment accorded the two preceding steers, was for three months and nine days fed a maintenance ration plus one-fourth of the productive feed above maintenance fed the first steer. Then followed 280 days of maintenance, a second feeding period of five months, and a final maintenance period of 110 days, which ended three months before slaughtering.

The "use of food" steers were fed half as much hay (alfalfa) as grain, and the grain consisted of corn chop, whole oats, and linseed meal 6:3:1. The other two groups were fed four-tenths as much hay as grain, and the grain consisted of corn chop and linseed meal 8:1. Weights, measurements, and analyses were made.

The authors conclude from their studies that "the mass of active body tissue, measured by the active body nitrogen, is a good medium of reference for maintenance costs. The relative surface area of cattle is a measure of the relative energy needs. The proportion of surface area to the two-thirds power of the live weight is shown to vary with the condition of the animal, but to be fairly constant for a given condition. The specific gravity of the blood of beef cattle is shown to be fairly constant with an average value of about 1.0510. Poorer nutrition seems to give a lower specific gravity. The proportion of blood to animal is shown to vary with the condition of the animal, but to be fairly constant for a given condition.

"An average consumption of 0.826 gm. of digestible nitrogen and 170 metabolizable calories of energy per 100 gm. of active body nitrogen per day are sufficient for maintenance. The consumption of energy per square meter of surface was 2,435 calories per day. Per kilogram of blood it required 3.31 gm. of digestible nitrogen and 667 calories of energy. In the customary units per 1,000 lbs., 0.889 lbs. of digestible protein and 12.92 therms of metabolizable energy sufficed for maintenance.

"Condition alone seems to have no effect upon the cost of maintenance. The cost of maintenance is high after a previous full-fed period, and the higher the previous plane of nutrition the greater this increase in cost. The cost of maintenance decreases with increasing age. The cost of maintenance is least in the spring and greatest in the winter. During the other seasons it is intermediate. A long maintenance trial seems to cause a lowering cost, but age and previous treatment are strong contributory causes. Great activity causes a higher maintenance cost. Poor thrift and high cost of maintenance seem to go together. The heavier the animal the greater the cost of maintenance in energy per unit of surface area. This is due to a relatively smaller surface area as well as to the heavier weight sustained."

Growth of pasture animals, FALKE (*Arb. Mitt. Deut. Gesell. Weidew. u. Viehzucht Leipzig, No. 1 (1914), pp. 31, fig. 1*).—The advantages of raising spring calves are pointed out, it being shown that during the first six months the most rapid and cheapest growth is made, that a summer's feeding on pasture puts calves in a position to undergo a rigorous winter, and that their subsequent gains are more rapid.

Calf-feeding experiment, 1914, P. H. FOULKES, A. ANDREWS, and J. B. GARNETT (*Field Expts. Harper Adams Agr. Col., Salop and Staffordshire, Rpt. 1914, pp. 19-21, fig. 1*).—Four lots of 4 calves each were fed 10 weeks as follows: Lot 1, 6 qt. of new milk daily per calf; lot 2, new milk gradually replaced by a gruel made from a home-mixed calf feed consisting of oatmeal, linseed meal, and corn meal 2:1:2; lot 3, new milk gradually substituted by a calf meal consisting of ground linseed, linseed cake meal, flour, and bean meal 5:14:2:2; and lot 4, 6 qt. separated milk, 2 to 3 oz. cod liver oil, and $\frac{1}{2}$ to 1 lb. crushed oats per day per calf. The average weekly gains per calf were 11.45, 7.1, 8.65, and 10.17 lbs., respectively, costing 7.25, 8.06, 5.34, and 2.8d. per pound of gain.

[**Sheep-breeding experiments**], P. H. FOULKES, A. ANDREWS, and J. B. GARNETT (*Field Expts. Harper Adams Agr. Col., Salop and Staffordshire, Rpt. 1914, p. 22*).—Ewes of the Improved Welsh breed were mated with pure-bred Rye-

land, Romney Marsh, and Improved Welsh rams. The Ryeland cross proved to be the most desirable, both as to vigor and fattening qualities.

Effect of dips on wool, B. G. ENSLIN (*Union So. Africa Dept. Agr. Rpt. 1913-14*, pp. 69-73).—Experiments in which sheep were treated with various dips are reported. It is said that while wool treated with caustic soda and sulphur in certain proportions will be dissolved, a dipping fluid made of the proper proportions will not damage the wool. The effect of all alkaline soda salts, when they are used improperly, is to destroy the spinning qualities of the wool, but it is said that the damage caused by the improper use of alkalis is hardly likely to be greater than that caused by the scab mites, for wool from sheep which have suffered from scab is brittle and structureless and has lost both its spinning and felting qualities.

[Pig] feeding experiments, O. W. H. ROULSTON ET AL. (*Dept. Agr. and Tech. Instr. Ireland, Rpt. Dept. Com. Irish Pig-Breeding Indus., 1914*, pp. 12, 13).—It was found that the average daily gain in weight made by a large number of pigs fed on barley, bran, or corn was practically the same. The pigs fed on barley produced a better quality of pork than those fed on corn.

In a feeding trial with 159 pigs, some fed during the summer and some in winter, on the average 4.13 lbs. of corn meal were consumed to produce 1 lb. of live weight, the maximum being 5.2 lbs. and the minimum 3.24 lbs. of meal. Pigs were fattened with less feed in summer than in winter. It was found that in a mixed feeding ration 4 lbs. of potatoes were approximately equivalent to 1 lb. of meal for fattening pigs. Though theoretically separated milk is about one-sixth of the value of corn meal, it was found that when it was fed to pigs with meal and potatoes it was actually worth almost one-third more than its theoretical feeding value, probably due to the greater relish with which the pigs consumed their feed.

A larger increase of weight was obtained in the early stages of fattening for the amount of feed consumed than in the later stages. Pigs fed either in summer or in winter on raw meals (steeped in water for from 1 to 12 hours) gave a higher daily gain than those fed on cooked meal, and the quality of pork was equally as good.

Swine-feeding experiments with a sugar feed, RICHARDSEN (*Landw. Ztschr. Rheinprovinz, 16 (1915), No. 23*, pp. 374, 375).—Successful experiments are reported in which 24 kg. of a sugar feed daily per 1,000 kg. live weight were fed in addition to a basal ration of corn meal and fish meal and blood or meat meal. The sugar appeared to increase the digestibility of the entire ration and to improve the quality of the flesh.

The value of fish and meat meals for fattening pigs, G. MARTINOLI (*Rev. Centro Estud. Agron. y Vet., 7 (1914), No. 72*, pp. 258-270; *abs. in Internat. Inst. Agr. [Rome], Mo. Bul. Agr. Intel. and Plant Diseases, 6 (1915), No. 3*, pp. 445, 446).—From results obtained in experiments comparing the relative feeding value of fish and meat meals it was concluded that in fattening pigs from the earliest age fish meal proved of value in developing the skeleton and in stimulating the appetite and the processes of assimilation. The animals fed on fish meal grew more rapidly than those fed on meat meal, and they were of superior quality. Neither the fish nor meat meal imparted any particular smell or taste to the flesh.

Artificial impregnation of mares, O. VON NEMESHEGNI (*Deut. Landw. Tierzucht, 18 (1914), No. 32*, pp. 383, 384, fig. 1).—A number of successful trials in artificially impregnating mares are reported. The results show that 5 cc. of the spermatic fluid is sufficient to impregnate one animal.

Care and training of trotters and pacers, A. C. THOMAS and W. H. SHIELDS (*Chicago: Chicago Horseman Newspaper Co., 1915, 3. ed., pp. 176, figs. 6*).—

The topics discussed in this book are the suckling colt, the weanling colt, making speed with yearlings, preparing for 2-year-old futurities, 3-year-olds, shoeing colts, defects in gait, types of shoes, feeding, grooming, and other related subjects.

The historical development of poultry husbandry in Germany, A. BEECK (*Jour. Amer. Assoc. Instr. and Invest. Poultry Husb.*, 1 (1915), No. 8, pp. 57-60, 61, 62).—A résumé of the development of the poultry industry in Germany.

A poultry survey of the city of Ithaca, O. B. KENT (*Jour. Amer. Assoc. Instr. and Invest. Poultry Husb.*, 1 (1915), No. 6, pp. 45-47).—Data are given on the sources of supply and the consumption of eggs and poultry in Ithaca, N. Y.

Animal food for poultry, H. W. JACKSON (*Jour. Amer. Assoc. Instr. and Invest. Poultry Husb.*, 1 (1915), No. 7, pp. 53, 54).—The author reviews available experimental work on feeding animal food to poultry, in which it appeared that meat-fed chicks made quicker and cheaper gains than others, regardless of size, and that chicks started on a ration deficient in animal food never regained their lost ground. He also reports his own experiments, in which hens without meat generally began laying before meat-fed hens and maintained their position for weeks and even months on such rations. He concludes that although the work done by most investigators has usually shown a decided superiority for the meat-fed laying hens, there is sufficient evidence the other way to warrant further investigation. In the fattening of fowls animal food has appeared to be essential to the best results, except when milk has been used, but of the various sources there seems to be little preference aside from convenience or economy.

The substitutes for animal food in common use are milk, milk albumin, or dried milk, vegetable sources of protein, and bone ash or phosphate sources. Milk albumin has not generally given good results. Milk, sour or otherwise, has given conflicting results. Vegetable protein when used under favorable conditions has often given as good results as when protein from animal sources has been used. Results of feeding bone ash or some carrier of phosphorus indicate that some of the advantage that has been claimed for animal protein may possibly be due to the mineral matter contained in the meat scrap or cut bone.

The value of mineral elements in poultry feeding, M. A. JULL (*Jour. Amer. Assoc. Instr. and Invest. Poultry Husb.*, 1 (1914), No. 2, pp. 1-3).—Experiments are cited which show that mineral elements are essential for the functioning of the vital processes as well as for the development of bone and eggs.

A résumé of chick feeding, CLARA NIXON (*Jour. Amer. Assoc. Instr. and Invest. Poultry Husb.*, 1 (1915), No. 6, pp. 47, 48).—This summarizes the principal results of chick feeding experiments at the various experiment stations.

Report of second twelve months' poultry laying competition, 1913-14, at Harper Adams Agricultural College, Newport, Salop, W. BROWN (*Field Expts. Harper Adams Agr. Col., Salop and Staffordshire, Rpt. 1914, pp. 83, figs. 6*).—This reports a second egg-laying competition (E. S. R., 31, p. 472) in which the various breeds of poultry were compared.

It was found that a steady, though small, amount of fish meal tends to produce a constant supply of eggs. The amount used was only 2.4 per cent of the total feed given. It is believed to be a mistake to give a full meal in the afternoon, since this tended to increase the number of soft-shelled eggs. The birds yielded a larger number of eggs if they were fed gradually during the day and given only a light feed at night. They consumed about 89.05 lbs. of feed per bird during the 12-months period, the heavy breeds consuming 91.07 lbs. per bird and the light breeds 86.55 lbs.

Inbreeding.—Its effect on vigor and egg laying, J. DRYDEN (*Jour. Amer. Assoc. Instr. and Invest. Poultry Husb.*, 1 (1915), No. 3, p. 19).—The author reports the results of his studies at the Oregon Experiment Station.

"From different matings where the son was bred to the mother, the pullet offspring showed a lower average egg yield than others not inbred. There was greater variability in production from the inbred pullets; that is, there was a wider range between the highest and lowest individual records than was the case with those not inbred. The vigor of the laying stock as shown by the mortality records was lowest in the inbred stock. The vigor of the offspring as shown by the mortality records of the chicks was lowest in the inbred stock. There was a lower fertility of eggs in the inbred stock. So far as fixing the character of egg production is concerned, inbreeding proved a failure."

The author states that in all his experiments with heavy layers, with one or two exceptions, a high record hen has never been secured by inbreeding or line breeding. The average result from inbreeding has been lower than from outbreeding.

Additional data on effect of castration in domestic fowl, H. D. GOODALE (*Jour. Amer. Assoc. Instr. and Invest. Poultry Husband., 1 (1915), No. 3, pp. 23, 24*).—This continues work conducted at the Oregon Experiment Station and previously noted (E. S. R., 29, p. 69).

It was found that "castration of the male brings about comparatively small changes in the secondary sexual characters. A capon is externally like the male, except that the comb and wattles remain small for a long time. Moreover, they do not as a rule crow or tread the hens. However, in some capons kept for a number of years the comb and wattles began to grow after eighteen months of age, eventually reaching a large size. These birds crow and exhibit sexual reactions. Castrated drakes, too, develop the plumage of the normal male. Those castrated completely possess one peculiarity, however, in that they do not assume the summer plumage, but, although molting frequently, always retain the so-called breeding plumage.

"On the other hand, the female, whether duck or fowl, from which the ovaries have been completely removed always develop male characters in large measure, though the degree to which these characters develop varies somewhat. In some individuals of each species the assumption of the male plumage has been practically complete. The castrated pullets look very much like capons, but have short legs. Sometimes, however, the comb and wattles become relatively large. The reason for this, perhaps, is to be found in a compensatory hypertrophy of the Wolfian body and duct observed in one instance, which seems to persist in some normal females for some months at least. It is quite possible, too, that the comb and wattles of the male owe their development not so much to the spermatogenetic tissue as to the epididymis. In ducks, after the removal of the ovary, the plumage sometimes becomes exactly like that of the male. However, in no instance has it been observed that the color of the upper mandible became like that of the drake, nor has a duck been observed which developed the male's voice, though in some instances they are unable to produce a normal 'quack.' In some instances, too, the castrated ducks develop the summer plumage. There is, however, a class of females which after castration do not develop typical male plumage, but acquire a distinctive type, which is made up of numerous feathers of the male breeding plumage type and a second type bearing a close resemblance to the feathers of the male's summer plumage. In some sections these last are often like those of the female. These females are undoubtedly constitutionally different from the others. Thus far all pure-bred females have belonged to the types just described, while those females which develop the most perfect male plumage have always been hybrids.

"In a number of instances the complete removal of the ovary has not been effected, but minute portions remained behind. In these instances the new

feathers which developed immediately after the operation were like those of the male, but those which developed still later were female. Many were partly male and partly female, the male portion in some instances being separated by a clear-cut transverse line from the female part. A regenerated ovary has been found in all such instances. In birds which were molting when completely ovariectomized the partly grown feathers exhibited the first sign of male characters about ten days after the operation, so that it seems probable that the change in the mode of development must take place almost immediately. . . .

"We may conclude, therefore, that while both the ovaries and testes produce internal secretions, their effect is quite different, that of the ovary being the most striking in that it is responsible for development of the female secondary sexual characters. Possibly, as a working hypothesis for birds, we may assume that the secondary sexual characters of the male, subject, of course, to the above observations on the comb, wattles, and crowing instinct, are common to each sex, but are modified in the female, under the influence of the ovary, into her characters. Hence, after castration the male characters develop while in the male no comparable change takes place."

On the rhythm of egg production, H. D. GOODALE (*Jour. Amer. Assoc. Instr. and Invest. Poultry Husbandry*, 1 (1915), No. 3, pp. 18, 19).—It has been observed at the Massachusetts Experiment Station that most hens lay for a period of several days and then skip one. The first day of a series the hen lays early in the morning. The time she lays the next day depends largely on the character of her particular rhythm. If the rhythm is such that she lays only every other day, she usually lays about the same time each day, i. e., 10 a. m., 0, 11 a. m., 0, 10 a. m., 0, 11 a. m. If she lays two days out of three, the first egg is laid during the morning and the second during the afternoon, i. e., 10 a. m., 3 p. m., 0, 10 a. m., 2 p. m., 0, 9 a. m., 1 p. m., 5 p. m., 0. As the period lengthens the number laid in the morning increases until the larger proportion are laid before noon. Thus, 8 a. m., 9 a. m., 10 a. m., 10 a. m., 10 a. m., 10 a. m., 9 a. m., 10 a. m., 9 a. m., 5 p. m., 11 a. m., 11 a. m., 5 p. m., 11 a. m., 11 a. m., 2 p. m., 2 p. m., 4 p. m., 0. There is, however, much variation.

Some hens lay every other day, or we may say, a $\frac{1}{2}$ rhythm, others $\frac{2}{3}$, that is, two days out of three, others $\frac{3}{4}$, and so on. None of these types are characteristic of any one hen. Many individuals, however, seem to center about a particular rhythm.

On the basis of winter egg production birds fall into three classes—high, mediocre, and zero producers. The dividing line between the high and mediocre producers came at about 30 eggs. There is great variation in the number of eggs laid by birds in the over-30 class. Broodiness, age, and time at which laying commences in the fall all influence the number of eggs laid. But aside from these factors birds of the same age, beginning to lay at approximately the same time, and which do not become broody, do not lay at the same rate.

With regard to rhythm and very high egg production, the curve of the winter egg production did not slope evenly to the base line, but formed a shoulder at 70 to 80 eggs. This shoulder is taken to be an indication, from a genetic standpoint, of a group of individuals differing genotypically in their capacity for egg production from the remainder of the high class. The existence of this group is thought to be due in part to the high-frequency pullets.

Various causes may interfere with the normal rhythm, such as environment, season, method of management, and internal factor, as broodiness.

It has been found that there are hens which never lay an egg, but which visit the nests according to a very definite rhythm. The hours of such visits fall into the same sort of rhythm as normal hens. These facts point to the

existence of some mechanism other than the formation and deposition of an egg which controls the extrusion of the egg. It is said that laying hens often visit the nest at the proper day and hour, but fail to lay. Such hens usually lay the day previous and the day after in regular routine, though at times they may pay two or more such nonproductive visits in succession.

The amount of carbon dioxid thrown off by eggs during the incubating process, H. ATWOOD and C. E. WEAKLEY, JR. (*Jour. Amer. Assoc. Instr. and Invest. Poultry Husb.*, 1 (1915), No. 4, pp. 26-28).—Work is reported from the West Virginia Station in which the carbon dioxid thrown off by nine eggs from three hens during incubation was determined.

It was found that as the incubating process goes on the carbon dioxid thrown off increases very rapidly. The loss of carbon dioxid during the last five days of incubation was about five-eighths of the total loss of carbon dioxid, twice as much as that given off in the third five days, ten times as much as that in the second five days, and almost fifty times as much as that in the first five days. In an incubator this carbon dioxid must be removed or at least kept below a certain maximum, which some investigators (E. S. R., 31, p. 172) have found to be 150 parts in 10,000. If this maximum is not to be exceeded, 100 fertile eggs will require 165 cu. ft. of fresh air to be passed over and around them on the twentieth day to keep the embryos from smothering.

A considerable excess of air was used in this test with no ill effect.

Peacock-guinea fowl hybrids, D. BRENTANA (*Mod. Zooliatro, Parte Sci.*, 25 (1914), No. 11, pp. 1001-1009, figs. 2; *abs. in Internat. Inst. Agr. [Rome], Mo. Bul. Agr. Intel. and Plant Discases*, 6 (1915), No. 2, pp. 280, 281).—An account is given of the hybridization between two guinea fowl hens and a peacock.

The hybrids resembled the peacock more in their general slender form, especially in the head and neck, although there was a noticeable absence of all the characteristic appendages of the head and the train was much reduced. The plumage exhibited striping, which is to be considered as the primitive type. It was of a dark fawn with black stripes in the lower part of the neck, becoming paler fawn with black specks in the region of the thorax, abdomen, and flanks.

Bibliography [of poultry literature] (*Jour. Amer. Assoc. Instr. and Invest. Poultry Husb.*, 1 (1914), No. 2, pp. 5-7).—A bibliography of poultry literature published between July, 1913, and July, 1914.

DAIRY FARMING—DAIRYING.

The value of barley for cows fed alfalfa, G. H. TRUE, F. W. WOLL, and E. C. VOORMIES (*California Sta. Bul.* 256 (1915), pp. 423-445, figs. 7).—Two lots of seven cows each, as nearly alike as possible with reference to breed, age, weight, and production, were fed during three periods of three weeks each by the reversal method, one lot receiving 30 lbs. per day of green alfalfa and alfalfa hay ad libitum, while the other lot received in addition approximately 1 lb. of barley to every 5 lbs. of milk produced by the cow.

During the alfalfa-barley periods the cows consumed an average of 210 lbs. of green alfalfa, 141 lbs. of alfalfa hay, and 42 lbs. of barley per head per week, and produced 183.3 lbs. of 3.6 per cent milk, or 6.65 lbs. of milk fat; during the alfalfa periods, 210 lbs. of green alfalfa and 153 lbs. of alfalfa hay, and produced 157.6 lbs. of 3.7 per cent milk, or 5.87 lbs. of milk fat.

Comparing the net increase in the cost of the rations incurred by feeding barley with the increased value of production, a profit of \$1.78 was secured as a result of adding barley to the alfalfa ration, on the basis of selling milk at 16 cts. per gallon and including the value of the gain in weight by the cows

at 5 cts. per pound. On the basis of butter fat sold at $33\frac{1}{2}$ cts. per pound, a loss of \$5.62 for the cows during the actual feeding of barley was obtained.

In a second and similar experiment with two lots of nine cows, fed during two periods of four weeks each by the reversal method, during the alfalfa-barley periods the cows consumed an average of 440 lbs. of green alfalfa, 95 lbs. of alfalfa hay, and 40.3 lbs. of barley per head per week, and produced 134.9 lbs. of 3.78 per cent milk, containing 17.3 lbs of solids and 5.08 lbs. of butter fat; during the alfalfa periods, 523 lbs. of green alfalfa and 98 lbs. of alfalfa hay, and produced 119.1 lbs. of 3.76 per cent milk, containing 15.1 lbs. of solids and 4.48 lbs. of butter fat. Larger gains in weight of the cows were made during the barley periods than when rough feed only was fed. The increase in the value of the products obtained as a result of feeding barley was not sufficient to pay for the grain fed, whether the calculations be based on whole milk at 16 cts. per gallon or butter fat at $33\frac{1}{2}$ cts. per pound.

The results of the two experiments show that "an immediate increase in production will be secured as a result of the grain feeding, but that this increase will not, as a rule, pay for the extra cost of the ration. On account of the increased production obtained and the residual effect of the grain feeding, as well as its favorable influence on the condition of the cows and their offspring, it may be concluded, however, that the practice of feeding grain to cows on alfalfa is economically sound and may be recommended. This holds true, especially, for heifers and young cows, as well as for heavy-producing animals which can not be brought to a maximum production on roughage only, even if this be as excellent and palatable a feed as green alfalfa or good alfalfa hay."

Prolificacy in the breeds of dairy cattle (*Guernsey Breeders' Jour., n. ser., 7 (1915), No. 7, pp. 18, 19, fig. 1*).—A comparison of the various breed associations as regards number of registrations, increases in registration during the past decade, and extent of importations.

Holstein makes new world's record (*Breeder's Gaz., 67 (1915), No. 25, p. 1207*).—It is said that the world's record for fat production has been broken by the Holstein cow Finderne Pride Johanna Rue, which has completed a record of 28,403.7 lbs., of milk containing 1,176.47 lbs. of milk fat in one year. This cow produced in seven days, at the close of her yearly test, almost as much fat as in her best seven days at the beginning of the test.

The dairyman versus the dairy, C. E. NORTH (*Amer. Jour. Pub. Health, 5 (1915), No. 6, pp. 519-525, fig. 1*).—This article relates the circumstances of a demonstration which had as its purpose a comparison of the work of two groups of dairy farmers producing milk at different times in the same dairies.

It is concluded that the dairyman is the chief factor and the dairy of secondary importance. The clean dairyman may be transported from dairy to dairy and can make clean milk wherever he goes. It is said that if all non-essentials or matters of secondary importance are eliminated, the factors which even alone are sufficient to produce under the conditions found in ordinary dairies a milk so clean that it will have with great regularity a bacterial count of less than 10,000 bacteria per cubic centimeter are as follows: Milking with dry hands into covered milking pails, the proper washing and sterilization of milking pails and milk cans, cooling the milk by placing the cans in tanks of cold water or ice water, regular laboratory testing of the milk for bacteria, and payments based on the laboratory tests.

The score-card system for the inspection of dairy farms (*Univ. Col. Reading, Dept. Agr. and Hort. Bul. 22 [1915], pp. XV+18, fig. 1*).—Part 1 of this bulletin consists of a discussion of the score-card system by J. Mackintosh, and part 2 contains a score card with explanatory notes.

A survey of the milk situation in Kansas, L. A. CONGDON (*Bul. Kans. Bd. Health, 11 (1915), No. 4, pp. 81-128, figs. 7*).—The topics discussed in this bulletin are bacteria in milk, adulteration, dairy inspection, the milk sediment test, pasteurization, analyses of milk, influence of foot-and-mouth disease on milk, etc.

The importance of milk sugars for the hygienic judging of milk, A. GABATHULER (*Ztschr. Fleisch. u. Milchhyg., 25 (1915), Nos. 7, pp. 97-100; 8, pp. 113-119; 9, pp. 135-140*).—It is stated that the least functional disturbance results in a lowering of the milk sugar content of the milk. At the beginning and end of the lactation period the milk sugar content is the lowest, while the middle milk is the highest, decreasing toward the end. Oestrus has little effect upon the production of milk sugar, and castration is without any noticeable effect. A salty flavor of milk is due not so much to the presence of sodium chlorid or other salts as to the diminution of the milk sugar content. It is recommended that in judging milk from a hygienic standpoint its lactose content should be taken into account.

On an epidemic of sore throat and the virulence of streptococci isolated from the milk, E. C. ROSENOW and V. H. MOON (*Jour. Infect. Diseases, 17 (1915), No. 1, pp. 69-71*).—An account is given of an epidemic of streptococcal sore throat, traced to an infected milk supply, which subsided when pasteurization of the milk was instituted.

"Virulent streptococci isolated from the milk showed selective preference for certain animal structures, such as joints, muscles, gall bladder, etc., as had the streptococci in strains isolated from articular and muscular rheumatism in man, and in certain 'laboratory' strains after they had acquired a certain grade of virulence. Furthermore, the organisms from milk resembled the rheumatic strains culturally and morphologically. Involvement of muscles and joints occurred in patients who were infected by the milk. These observations strongly suggest that infected milk, in addition to causing epidemics of sore throat, in which the symptoms are acute and marked, may be the source of streptococci of such virulence as to cause rheumatism and allied conditions in human beings."

The advantages and disadvantages of preservatives in food, W. G. A. ROBERTSON (*Jour. State Med., 23 (1915), No. 6, pp. 176-182*).—The author cites experiments and other authorities tending to show that the addition of small amounts of boric acid (0.2 per cent) to milk is not deleterious to the human economy. He suggests that the addition of this preservative to milk in minute amounts be allowed, thus avoiding the possibility of using milk which is undergoing decomposition.

Tables for blending milk and cream or different percentages of cream, MARGUERITE J. McNALLY (*[New Castle, Pa.]: Miller, Pyle & Graham, 1915, pp. 25*).—This is designed for the use of creamery and ice cream factory operators, milk dealers, and condensers. It contains complete tables for making an 80-lb. blend of any percentage from 8 to 30, inclusive. This is done by mixing cream testing from 15 to 46 per cent of fat with skim milk, or with any percentage of milk or cream from skim up to 30 per cent.

How to make creamery butter on the farm, W. J. and Mrs. McLAUGHLIN (*Minneapolis, Minn.: The Lakeland Press, 1915, pp. 96, pls. 3, figs. 8*).—A discussion of dairy-farm management methods, together with instructions for butter making on the farm.

The manufacture of cheese with selected ferments, F. SAMARANI (*Ann. R. Staz. Sper. Cascif. Lodi, 1913, pp. 13-23*).—The application of pure lactic ferments in the manufacture of Grana and some other cheeses is discussed. The milk is cooled, a culture of a lactic bacillus of great strength which has been

developed in whey is added at the rate of 1:1,000, and a temperature ranging from 35 to 40° C. maintained for at least 24 hours.

Blue-veined cheese, or Dorset "Vinny" (*Dairy*, 27 (1915), No. 318, p. 154).—The method of making blue-veined cheese, known as Dorset Vinny, is described.

Chemical examination of ghee, K. H. VAKIL (*Jour. Soc. Chem. Indus.*, 34 (1915), No. 7, p. 320; *abs. in Analyst*, 40 (1915), No. 471, p. 284).—Fresh samples of ghee, mainly from buffalo's milk, gave the following average analytical results: Butyrefractometer at 40° C. 44.35, saponification value 226.9, Reichert-Meissl number 23.05, and acid value 2.14.

Bibliography of dairy literature, compiled by A. BROSCHE (*Mitt. Deut. Milchw. Ver.*, 31 (1914), Oct., pp. 223-233).—This gives a bibliography of dairy literature published during a portion of 1914.

VETERINARY MEDICINE.

Epizootic abortion, S. STOCKMAN (*Jour. Compar. Path. and Ther.*, 27 (1914), No. 3, pp. 237-246).—It is stated that practically all of the domestic animals can be infected with *Bacillus abortus*, but that bovine abortion under natural conditions of infection is almost entirely confined to the bovine species. Although an animal of the bovine species may be experimentally or naturally infected with the ovine disease (vibrio of McFadyean and Stockman) it is unusual, so far as experience goes, to find a large number of cases of natural infection in bovine animals due to the vibrio. It appears that abortion in mares is due to members of a group of micro-organisms totally different from those which usually cause abortion in other species, but as yet the equine disease has not been the subject of as much study as the disease in other species.

Serum from an animal affected by Bang's bacillus will cause agglutination of the bovine bacillus, but it will not agglutinate the vibrio. The same is true with the other biological tests. The disease in bovines is essentially of a chronic nature. "Bovine abortion assumes epizootiological characters, while the ovine and equine diseases usually occur as enzootics, but this seems to arise more from the trade transactions and method of breeding to which the different species are subjected than from other causes. . . ."

"No great accumulation of virulent material occurs in any part of the body with the exception of the pregnant uterus of an affected animal. It follows from this that gross infection of pastures, stables, or cowsheds only takes place just before, during the act of, or subsequent to abortion." Infective material in the bovine disease may remain virulent for a period of many months outside the body of the living animal, on the pastures, or in the cowsheds. The infective material from the uterus of a cow is not excreted any considerable time before the act of abortion. In the ewe, however, a discharge containing vibrios may pass out on to the pastures from the genital organs a few days after infection, and many weeks before the animal is known to be infected. How long an animal which has aborted may remain infective (virulency of the causal microbe in the genital organs) has not been accurately determined. With regard to the cow, a large number of animals have got rid of the infected material from the genital organs from two to three months after the act of abortion.

Artificial immunization was made on several thousand animals. When a colossal dose of bacilli was injected subcutaneously into a nonpregnant animal and that animal became pregnant some two months later it did not abort. This finding might, however, be interpreted to mean that although bacilli may still be in the body the organism has become so resistant to them that they can not flourish even in the pregnant uterus.

The disease is believed to be disseminated in the bovine by way of the alimentary tract, but it is also theoretically possible that the cow may be infected when served. It seems very doubtful if the pregnant uterus of a noninfected cow can become infected by the bacillus of bovine abortion traveling up the genital organs from without as the bacillus of Bang is nonmotile. With the ovine disease the genital avenue of infection seems more probable.

For the diagnosis of the disease the complement fixation and agglutination tests give satisfactory results. See also previous notes (E. S. R., 29, p. 481; 30, p. 684). "In the application of serological methods to a herd or flock with the object of picking out the infected animals, weight must be given to the same considerations as in the case of the tuberculin test for a similar purpose."

As regards prevention, it is thought that state measures based on effective restrictions on the movements of infected animals would be ruinous to the business of farmers. By the serological methods it would be possible to establish infected cows in a herd, and where trained men are not available for this work or where there are no provisions for isolating infected animals before they abort or calve, an effort should be made to prevent gross infection by the immediate removal of infective material and by thorough disinfection of barns, etc.

Immunization, however, in addition to the above-mentioned general measures of prevention, is deemed the best method for solving the difficulty. Since trouble was experienced in regard to the transport and injection of large quantities of liquid culture and abscess formations were liable to follow its use, massive cultures are now prepared by growing on potato meat extract peptone bouillon agar containing salt, glucose, and glycerin. To wash the bacilli from the agar contained in ordinary medicine bottles, about 30 cc. of saline solution is added with a sterile hypodermic syringe. The bottle is shaken violently in order to rub all the bacilli from the agar, which breaks up into small portions, and the bacillary emulsion obtained in this way is passed through a strainer. Some thousands of animals have been inoculated without abscess formation due to extraneous contaminations during the operations.

"Two kinds of vaccine have been tried: Antiabortion A, consisting of living bacilli, and antiabortion B, consisting of bacilli killed by exposure to a temperature of 65° C. for half an hour. Only nonpregnant animals have received A. Only one dose of A was given, and the animals were not put to the bull, except in certain cases by error, for at least two months after inoculation. Antiabortion B was given to cows already pregnant, and a dose (half the growth on a culture bottle) was injected each month up to the sixth month of pregnancy. In both cases only badly infected herds were chosen for the observations. The herds were taken in groups in different parts of the country, and a local organization was set up in each case consisting of members of farmers' societies and veterinarians. . . .

"Over 3,000 inoculations have been carried out, but it has so far been possible to collect and tabulate the completed results in only one or two groups. The trials with vaccines A and B were in most cases carried out on the same farms, and the controls acted as such for both methods." The best results were obtained with vaccine A, although the animals inoculated with vaccine B showed a greater percentage of normal calving than did the controls or nonimmunized animals.

The biology of pseudoanthrax bacilli.—Contribution to the differential diagnosis of anthrax and pseudoanthrax bacilli, N. POKSCHISCHESKY (*Berlin. Tierärztl. Wchnschr.*, 31 (1915), No. 2, pp. 16, 17).—Two types of pseudoanthrax bacilli are described, (1) *typus pseudoanthracis* which gives a luxuriant growth in agar and gelatin stab cultures in the shape of thick

branchings and on potatoes grows as a red-brown layer, and (2) *typus anthracoides* which grows in agar and gelatin stab cultures as button-like colonies and on potatoes as a dirty-gray layer.

Anthrax precipitating sera react positively with both anthrax and pseudoanthrax bacilli, consequently the test can be regarded only as a group test. Anthrax and pseudoanthrax antigens show positive by the complement fixation test with pseudoanthrax and anthrax sera. On blood medium the pseudoanthrax bacilli show a definite hemolysis while anthrax bacilli do not. Pseudoanthrax bacilli are not pathogenic except possibly for mice. Passage tests did not increase the virulence of the bacteria.

A butcher slaughtering one of the hogs examined became infected and died, having all the symptoms of anthrax. The significance of pseudoanthrax bacillus infection in man is discussed.

An unusual result following anthrax vaccination and a lesson, M. P. RAVENEL (*Amer. Vet. Rev.*, 46 (1915), No. 6, pp. 634-638).—An account of the death of 41 animals treated with anthrax vaccine. The courts decided that the manufacturers of the vaccine were not at fault.

Eradication and treatment of the foot-and-mouth disease according to my system, IV, L. HOFFMANN (*Heilung der Kranken und Vertilgung der Maul und Klauenseuche nach meinem System, IV. Stuttgart: Stähle & Friedel, 1914, pp. 409-502*).—A description of the author's experience in treating and eradicating foot-and-mouth disease with euguform in the community of Zuoz (Graubünden).

Further observations on the effect of quinin in rabies, V. H. MOON (*Jour. Infect. Diseases*, 16 (1915), No. 1, pp. 58-62).—This is a report of experiments in continuation of those previously noted (E. S. R., 29, p. 883).

It is concluded that quinin has failed to be regularly effective as a cure or preventive of rabies in animals. Given in the latter stages of hydrophobia in two human cases, it produced no significant results, but it appears to retard somewhat the development of street rabies if given in large doses during the incubation period. "The results indicate that the organism which causes rabies is influenced in some degree by quinin. This is significant as showing that the organism is susceptible to therapeutic measures, and gives reason to hope that some drug may be found which will be of value in the treatment of hydrophobia."

Experimental study of the distribution and habitat of the tetanus bacillus, W. NOBLE (*Jour. Infect. Diseases*, 16 (1915), No. 2, pp. 132-141).—"The tetanus bacillus appears in the intestines of many normal animals, especially of the herbivora, but apparently it seems impossible, with the methods at our disposal, to detect it there unless it is present in relatively large numbers. Experimental evidence shows that the tetanus bacillus may multiply in the intestines of such animals. The intestines, or rather the intestinal contents of certain individual animals, seem to offer especially favorable conditions for the growth of the tetanus bacillus; such animals are 'tetanus carriers' comparable, in regard to the distribution of the organism, with typhoid or cholera carriers among human beings.

"The presence of tetanus spores in soils, street dust, fresh vegetables, and on clothing and the skin is undoubtedly due to fecal contamination."

Some further investigations on hog cholera, K. UHLENHUTH, H. GILDEMEISTER, and K. SCHERN (*Arb. K. Gsndhtsamts.*, 47 (1914), No. 2, pp. 145-239).—A continuation of investigations published in 1907.

In the work previously reported no cognizance was taken of the fact that disinfectants act less effectively in solutions, etc., containing protein substances than they do in aqueous solutions. In these experiments phenol, corrosive sublimate, antiformin, ozone (all used in the previous experiments), and milk

of lime, calcium hypochlorite, cresol soap solution, lysol, soda and soap solution were tested on urine filtrates from diseased animals and serum (virus) filtrates. After the urine or virus was kept in contact with the disinfectant for specified lengths of time, it was injected intramuscularly into shoats about eight weeks old.

One per cent corrosive sublimate solution was not able to destroy the virus, a protein-containing fluid, with certainty by a three-day exposure. The virus in the urine, however, was considerably weakened on a 15-minute exposure and in one case was destroyed. Carbolic acid (5 per cent) did not affect the virus in urine on a 15-minute exposure. No tests were made with the virus serum because it had been previously found by Uhlenhuth and others that the virus is not killed after several days of exposure. A 2 per cent antiformin solution will kill the serum virus in two hours and a 5 and 10 per cent solution will kill after one hour. The urinary virus was killed within 15 minutes by 2 per cent antiformin, but with a 5 or 10-minute exposure it was still fully virulent. In one-half hour exposure to a 3 per cent solution of cresol soap solution, the serum virus filtrate was almost or entirely destroyed, while the urinary virus was regularly destroyed in 15 minutes. Three per cent lysol solution did not regularly kill the serum virus filtrate in one hour. Milk of lime, used in the same proportion as virus, killed the urinary virus in 15 minutes but gave irregular results with the serum virus. Calcium hypochlorite (1:5 and 1:20) destroyed the virus from both sources in 15 minutes. Virus was not killed by either soda or soap solution. The findings as regards the value of 6 per cent cresol soap solution confirmed those of Dorset reported some time ago.

The filtered urinary virus when kept outside of the animal body is much less stable than the serum virus. There are instances, however, where the serum virus, a protein-containing fluid, when kept in the ice box loses its virulence much sooner than the urinary virus. This may in part be due to the copresence of antibodies in the serum. The virus in urine filtrates was destroyed by heating to 65 and 58° C. for one hour, but heating one-half and two-thirds hour at 58° did not destroy its disease-producing power for shoats. The virus in both urine and serum was very labile toward putrefactive processes. Five and nine-hour exposures to sunlight had no noticeable effect on the virus. In the carcasses of pigs stored in a cool place the virus was still active after 33 days. Exposure of virus to an oxygen-free atmosphere (carbon dioxide, hydrogen, or illuminating gas) in most instances did not affect the potency of the virus.

In experiments on the behavior of the virus in the body it was found that the urine of a pig collected five days postinfection was capable of infecting shoats. The purulent material from the skin lesions of experimentally infected shoats when transferred to healthy shoats produced the disease. This as well as the nasal secretion is deemed of particular importance as to contact infection.

The development of the trachoma-like bodies was studied morphologically, and scrapings from the conjunctivas of affected pigs were implanted in the conjunctivas of healthy pigs and other animals, i. e., monkeys, rabbits, guinea pigs, goats, dogs, horses, bovines, and an ass. In all animals, with the exception of the pig, the results were negative. One hundred sound normal shoats were examined for the presence of trachoma bodies. Cellular inclosures were also found in 3 per cent of pigs free of hog cholera. The eye secretions as well as serum virus filtrates and fresh feces from cholera hogs when smeared on the conjunctivas of pigs apparently will produce the disease.

No immunity could be produced by introducing vaseline virus ointment into the conjunctival sack of pigs or by rubbing it in the skin. Ununiform results were obtained by injecting virus in the ligated tail. Tests made for obtaining

an attenuated virus were tried on immune pigs, but the results were unsatisfactory. Somewhat better results for obtaining attenuated virus were given by the simultaneous method. The animals were infected by way of the conjunctiva with virus and were given immune serum intramuscularly.

With the idea of preparing immune serum at lower cost the urinary filtrate of cholera hogs was tried. The results with horses were negative, but in the case of hogs antisera were obtained which were as potent as the ones produced with virus serum filtrates. Uremic symptoms were noted in some of the animals treated with large amounts of urine filtrates. Organ extracts were also tried.

The lungs, liver, spleen, kidneys, lymphatic glands, mucosa of intestines, and intestinal contents of all hogs coming to autopsy were given bacteriological examination. The bacteria were studied in milk, litmus milk, Löffler's malachite green, Barsiekow's solution I and II, Hetsch's solution, glucose and lactose bouillon, and neutral red and orcein agar, and as regards their biological and serological behavior. Out of 90 animals segregated in special cages only 14 showed the *Bacillus suispestifer*, while 15 out of 20 pigs which were allowed to run with other infected hogs showed it. The organisms at first did not agglutinate with pestifer and paratyphoid B sera. It seems possible that secondary bacteria present in hog cholera migrate into the blood stream of affected animals.

In addition to the paratyphoid group of bacteria, the bacteria of the hemorrhagic septicemia group may also be present. The greatest percentage of *B. suispestifer*, *B. enteritidis* (Gärtner), and *B. suissepticus* were found in the stables where the animals were allowed to run together. The *B. suissepticus* isolated was virulent for mice, guinea pigs, rabbits, and pigs. Variable results were obtained with *B. suispestifer* and *B. enteritidis* (Gärtner) with shoats. In some cases the injection of *B. suispestifer* produced a disease similar to hog cholera, especially the intestinal changes. *B. suispestifer* (Voldagsen), according to Dammann and Stedefeder (E. S. R., 24, p. 390), and the Glässer bacillus, i. e., *B. typhi suis*, do not produce indol, nor is litmusmannite-nutrose solution (Hetsch) affected. The organisms were pathogenic for pigs, but large doses were necessary. The best route of infection was per os. Shoats rendered immune against the filterable virus could only be infected (either by the intravenous or os route) in a few instances. Spontaneous infection tests showed that these bacteria are not in any way infectious, as one is led to believe from the work of Pfeiler and Kohlstock (E. S. R., 32, p. 378) and Weidlich (E. S. R., 32, p. 83).

The bacteria isolated could be differentiated by culture studies and the agglutination tests. Notwithstanding this, some Voldagsen cultures were found labile in their behavior when examined culturally as well as serologically. In some cases Voldagsen strains were influenced soon after isolation by paratyphoid B and pestifer sera.

The behavior of Glässer bacteria with specific sera is also discussed.

When to vaccinate against hog cholera (*California Sta. Circ. 132 (1915), pp. 4, fig. 1*).—This circular gives advice concerning the early recognition of hog cholera, the methods for immunization, means of preventing the spread of the disease, and an announcement of the sale of antihog-cholera serum by the University of California.

Some diseases of the respiratory tract of the horse which resemble glanders, E. JOEST (*Ztschr. Infektionskrankh. u. Hyg. Haustiere, 16 (1915), No. 4, pp. 239-263, figs. 10*).—The pathological changes in the upper respiratory tract dealt with include tuberculosis of the mucous membrane of the nares, cicatrices of the nasal mucous membrane, tumor-forming amyloidosis of the nasal vesti-

bule, tubercle-like hemorrhagic centers of the nasal mucous membrane in purpura hemorrhagica, and marantic ulcers caused by pressure in the larynx.

Microfilariasis of the horse in Turkestan, W. I. YAKIMOW, N. I. SCHOCHOS, P. M. KOSELKIN, W. W. WINOGRADOW, and A. P. DEMIDOW (*Ztschr. Infektionskrank. u. Hyg. der Haustiere*, 16 (1915), No. 4, pp. 275-286, fig. 1).—An account of studies of the disease termed by the authors Turkestan microfilariasis, including its clinical appearance, hematological investigations, description of the microfilaria, and remedial measures. The form occurring in Turkestan apparently represents a new species, to which the name *Microfilaria ninu kohl-yakimovi* is given.

A list of 21 references to the literature is included.

RURAL ENGINEERING.

Tenth biennial report of the state engineer to the governor of Idaho (*Bien. Rpt. State Engin. Idaho*, 10 (1913-14), pp. 422, figs. 5).—This report covers the operations of the state engineer's office for 1913 and 1914, paying special attention to irrigation and measurement of stream flow and including a report on duty of water investigations by D. H. Bark, noted below.

Irrigation investigations in Wyoming, 1913-14, AUGUSTA F. JOHNSTON (*Cheycenne: State of Wyoming*, 1915, pp. 14).—This report, based on cooperative irrigation experiments carried on by the Office of Experiment Stations of this Department and the State of Wyoming, reviews the work at the experimental farms and discusses irrigation extension work in the State.

Water conservation and irrigation (*Rpt. Comr. Water Conserv. and Irrig. [N. S. Wales]*, 1912-13, pp. 72, pls. 4).—This report covers government work relating to irrigation and water conservation for the years 1912 and 1913.

Duty of water investigations, D. H. BARK (*Bien. Rpt. State Engin. Idaho*, 10 (1913-14), pp. 63-177, figs. 5).—These investigations (E. S. R., 29, p. 180) have been continued and conducted in cooperation with the Office of Experiment Stations of the U. S. Department of Agriculture, to cover four seasons. Points not brought out in the previous report are summarized as follows:

Factors and conditions tending to decrease the duty are "porous soil, infertile soil, cheap water, careless use, poorly prepared land, small irrigation heads, poorly constructed leaky ditches, continuous-flow method of delivery, lack of cultivation, and large acreages of alfalfa and pasture and other crops with large water requirements." Factors and conditions tending to increase the duty are "deep soil of fine texture, an underlying strata of hardpan, expensive water, careful, skillful use, well-leveled land, large irrigation heads, short runs, use of rotation systems, diversification of crops, well-constructed irrigation systems with small transmission losses, fall plowing and intensive surface cultivation, and large acreages of winter grain, cultivated crops, and orchard and other crops of low-water requirements.

"The amount of water required by a project depends upon the duty of water at the land, losses in reservoirs where water is stored, transmission losses from the point of diversion to the land to be irrigated, and the proportion of a project that is ultimately irrigated. The required duty for a crop on any soil can be roughly determined by ascertaining how many irrigations the crop will require during the season and the amount of water the soil will require per irrigation. . . . A sufficient quantity should be delivered to each individual over and above 2 acre-feet, so that he may, if unavoidable, waste not to exceed 12.5 per cent of the water delivered to him. . . . The light summer rainfall common to south Idaho has but little effect on the amount of irrigation required. . . . Fall plowing tends to increase materially production and decrease

water requirements. Grains and cultivated crops in general require less irrigation water than the other common crops of south Idaho. . . . Grains require the largest amount of water at the flowering or soft-dough stages. . . . Alfalfa has a decided tendency to increase in yield as the amount applied is increased until at least as much as 4 acre-feet per acre have been applied. While some crops increase in yield as the amount of water applied is increased, the increase in yield is rarely proportional to the increase required in the amount of water. The average waste from grain fields has been 35.3 per cent and 19.1 per cent from alfalfa. . . . The average length of the irrigation season for alfalfa for the four years of the investigation was 97.6 days, and 42.5 days for grain. . . .

"Sufficient water for the production of profitable and nearly maximum crops must be delivered to the individuals in order that a project may be successful, but a higher duty is justified in cases where water is very valuable and land comparatively cheap than where water is cheap and the land is valuable. . . .

"Ninety per cent of a normal Idaho project is irrigated each year. The total waste and unirrigated areas seldom equal 10 per cent. Where rotation systems are used the interval between rotations should seldom exceed from ten to fourteen days.

"There are now at least 163 electrically operated pumping plants in the vicinity of Weiser and Payette. The plants tested during 1913 pumped varying amounts of water, the amounts pumped per acre ranging from 0.4 to 5.99 acre-feet. The costs of the power for pumping varied from 54 cts. per acre-foot to \$6.50, and per acre irrigated from \$1.77 to \$7. There is not sufficient incentive to save water where a flat season rate is paid for power. The investigation indicates that the cost of lifting water over 100 ft. with small plants is at present prohibitive. Serious loss and waste of power is now taking place in many instances due to faulty design and cheap, careless installation of the plants. Small and medium-sized plants should develop efficiencies of at least 50 per cent, and only such plants as can be guaranteed to do this or better should be installed.

"Successful irrigation in Idaho under present economic conditions demands that at least 2 acre-feet per acre be supplied for, and retained upon, each irrigated acre."

Irrigation works in Italy, L. LUGGI (*Jour. Dept. Agr. Victoria*, 12 (1914), No. 10, pp. 577-600, figs. 11; *abs. in Internat. Inst. Agr. [Rome], Mo. Bul. Agr. Intl. and Plant Diseases*, 6 (1915), No. 1, pp. 43-45; *Jour. Roy. Soc. Arts*, 62 (1914), No. 3228, pp. 940-943).—This article reviews the irrigation situation in Italy, with particular reference to the storage, distribution, and economic use of irrigation water.

About 3,458,000 acres of land are under irrigation, derived from wells, streams, and stored rain water. Where land can be superirrigated, it is stated that about 284,210 to 355,263 cu. ft. of water are required per acre, at a cost of about \$1.50 to \$3.50. The water is applied in rotations every 15 to 20 days at the rate of from 11,368 to 14,210 cu. ft. per acre. Water is applied at the rate of about 213,158 cu. ft. per acre to irrigated meadows. In the Roman Campagna where the land is less permeable than in Lombardy the water necessary during the dry season for irrigated meadows varies from about 245,000 to 350,000 cu. ft. per acre, and is applied at the rate of about 17,500 to 21,000 cu. ft. every 10 to 12 days. In the southern Provinces which receive 7 to 8 in. of rain during the growing season between March 15 and May 15 it is stated that irrigation water may be profitably applied at the rate of about 28,000 to 35,000 cu. ft. per acre in four irrigations.

The conclusion based on Italian experience is that irrigation prevents a complete loss of the crops in years of drought. "In normal years it affords a

very substantial profit to the farmers who cultivate meadow lands, and this increase of profit is certain, even if only grass can be grown, provided that the water can be got at the rate of \$1.90 to \$2.30 per acre per year, but where cereals can be cultivated, even with water at \$5.40 to \$7 per acre, there is still a good profit, besides the advantage of never completely losing a crop. On the other hand, irrigation works on a large scale are not profitable to the administration of the canals during at least the first thirty years, thus these undertakings require great help from the state during this trying period."

Working data for irrigation engineers, E. A. MORITZ (*New York: John Wiley & Sons, Inc., 1915, pp. XIII+395, figs. 46*).—This is a handbook of working data, intended for the use of irrigation and hydraulic engineers.

The major portion of the book consists of tables and diagrams. Before entering into a detailed explanation of these, the various features of irrigation engineering are briefly discussed, particularly with reference to gravity irrigation. "To this end, the usual steps in the development of an irrigation project are taken up in the order of their sequence, and data are presented that are of assistance in arriving at the proper conclusions."

The subject matter is presented in the following chapters: Examination and reconnoissance, investigations and surveys, design of irrigation structures, hydraulic diagrams and tables, structural diagrams and tables, miscellaneous tables and data, and specifications.

The author states that a considerable portion of the material is original and that most of the remainder was taken from the publications and records of the U. S. Reclamation Service. Some of the material has been noted from time to time in the *Record* from engineering periodicals.

Land drainage, J. L. PARSONS (*Chicago: The Myron C. Clark Publishing Co., 1915, pp. XI+165, figs. 36*).—It is the author's purpose to cover the subjects connected with the successful drainage of agricultural lands by open and closed drains. The information is intended for both experienced and inexperienced drainage engineers, drainage contractors, landowners, and drainage district officials. The subject matter is presented under the following chapter headings: Preliminary drainage surveys; the design of tile drains; tile drain outlet walls and inlets; design and maintenance of open drains; plans, reports, and records; the estimate of costs of drainage systems; the preparation and enforcement of drainage specifications; the division of costs of drainage systems; and the quality and inspection of drain tile.

Florida Everglades (*U. S. Senate, 63. Cong., 2. Sess., Doc. 379 (1914), pp. 148, pls. 7, figs. 63*).—This is the report of the Florida Everglades engineering commission to the board of commissioners of the Everglades drainage district and the trustees of the internal improvement fund of the State of Florida.

The commission's conclusion, based on its study of ascertained facts, is "that the drainage of the Florida Everglades is entirely practicable and can be accomplished at a cost which the value of the reclaimed land will justify, the cost per acre being very small. The solution of the Everglades drainage problem is primarily dependent upon the disposition to be made of the flood waters entering Lake Okeechobee from the north. These flood waters under present conditions pass over the south rim of the lake and spread over the Everglades, placing that great area under servitude of the surplus waters of the northern watershed. . . . The Everglades can best be relieved of this servitude by diverting the flood waters through a canal of adequate capacity occupying the shortest practicable route to the Atlantic Ocean or an inlet thereof. . . . With these extraneous flood waters diverted as indicated, the problem of draining the Everglades is reduced to proper provision for carrying off the precipitation

upon them. This can be accomplished by adding to the main canals which now traverse this territory—canals now surcharged with waters flowing out of Lake Okeechobee.”

The suggested improvement includes 390 miles of canal draining 2,095 square miles.

Maps, tables, and charts showing in detail the data obtained by the investigation are also included.

Water conveyance and drainage works (*Verlag Burgerl. Openb. Werken Nederland. Indië, 1911, pt. 4, A, pp. VIII+279, pls. 32*).—This report describes drainage works, including river improvements, and deals also with the conveyance of water in channels, both for drainage and irrigation.

Preliminary estimating of canal excavation, L. M. HAMMOND (*Engin. Rec., 71 (1915), No. 5, pp. 146, 147, figs. 6*).—Three typical prism sections are worked out in detail, formulas are derived, and tables and forms of notes are suggested to expedite the work.

Rock-fill dam with some extraordinary foundation problems, M. C. HINDERLIDER (*Engin. News, 73 (1915), No. 14, pp. 660-664, figs. 7*).—The construction of a rock-fill irrigation dam across a narrow gorge in southern Colorado is described. As originally designed, the spillway was over an adjoining ridge which on investigation proved to be of porous formation with the bedrock sloping way from the dam.

“For the purpose of intercepting the seepage from the reservoir through this material overlying bedrock, a concrete diaphragm 2 ft. thick at the base and 1 ft. thick at the top was carried from bedrock upward to a point 10 ft. below high-water line in the reservoir. . . . Above this concrete diaphragm the trench was filled to the surface with equal parts of clay and sand mixed in a concrete mixer and run into the trench in the form of puddle.”

The spillway was transferred to the dam proper.

Concrete chute drops water 130 feet from canal to reservoir, D. W. COLE (*Engin. Rec., 71 (1915), No. 15, pp. 456, 457, figs. 6*).—A lined channel of the Truckee-Carson project in Nevada has a cantilever upturn at the discharge end and a long weir at the head to regulate the water level in the main canal within the desired limits. A curious hydraulic phenomenon is the disappearance of the back-water wave when the chute begins to operate normally.

New type of gate for regulating adjacent water levels operates automatically (*Engin. Rec., 71 (1915), No. 10, pp. 304, 305, figs. 4*).—A type of automatically operated regulating gate which has been used in drainage canals by the drainage department of the Province of Buenos Aires, Argentina, is described and diagrammatically illustrated.

“The design is based on the principle of momentary points of rotation, so that for each rise in water level, dh , above a predetermined elevation, the gate has a rotation $d\phi$ in respect to a momentary point. Consequently, when the gate is full open, that is, when the water level has risen a height h , it has turned an angle ϕ and the point of rotation has traveled a distance s along an arc. To prevent the gate from overtravel, and to insure the automatic closing, a stopping arrangement limits the tilting of it.”

A modified type of this gate substitutes a roller on a piece of curved track for the lower lever arm.

Water supplies, S. and E. K. RIDEAL (*London: Crosby Lockwood & Son, 1914, pp. XII+274, pls. 24, figs. 10*).—It is the purpose of this book to summarize the science and practice of modern water supply and water purification, and it deals primarily with the purification, filtration, and sterilization of water supplies.

The subject matter is presented under the following chapters: Pure water— inorganic constituents of natural waters, animal and vegetable impurities, sources of water supply, distribution, storage, preliminary purification, sand filtration, mechanical filtration, softening of water, sterilization, electrical modes of sterilization, and analysis and interpretation of results.

Water supplies in the Philippine Islands, A. J. COX, G. W. HEISE, and V. Q. GANA (*Philippine Jour. Sci., Sect. A*, 9 (1914), No. 4, pp. 273-411, pls. 5).—It has been attempted in this paper to classify and arrange the information regarding the general status of water supplies in the Philippine Islands which has been collected up to date.

The data first show that "water from surface streams, no matter how well guarded, is not entirely satisfactory, since it is always subject to sudden contamination." Analyses of the water from shallow wells showed that nearly every well examined was dangerously polluted. It is stated that the best natural potable water is at present furnished by artesian wells. "The high chlorine content is one of the most notable general features of Philippine artesian waters. This does not necessarily indicate sewage pollution, but rather seepage from the ocean or contact with some underground salt deposits or impregnated rocks. The water from some of the artesian wells has been found to be too salty to drink." Flowing wells are deemed preferable because of the decreased danger of pollution, and artesian water has in general been quite satisfactory, both from the chemical and biological points of view. "In many instances where the quality left something to be desired the water was so much better than any other available supply that its use has been permitted."

Water-borne diseases are said to be more prevalent in the Philippines during the rainy season than at any other time, due to the washing of accumulated surface debris into the water courses. The three most important water-borne diseases are said to be typhoid, cholera, and entamœbic dysentery.

Methods for the purification of water supplies discussed are distillation, boiling, filtration, and the use of ultraviolet light, copper sulphate, and calcium hypochlorite. Boiling is considered to be the simplest and the most universal safeguard in so far as contamination of water due to living organisms is concerned. Tests of the copper sulphate method showed that in order to safeguard the supply against cholera the addition of copper sulphate in the ratio of 1 part per 150,000 parts of water (a strength considered undesirable for drinking purposes) acting over a period of four hours would be required.

Further data report in detail on water supplies for industrial purposes. It is stated that the need of a systematic water survey in the Philippine Islands is strikingly apparent and that "by combining the geologic information with all available chemical and biological data concerning the water occurring in any one district, it should not be difficult to establish safe limiting values for the normal constituents of water to serve as a basis in determining its fitness for any particular purpose."

The influence of the forest on the water supply, HENLE (*Jour. Gasbeleucht.*, 57 (1914), pp. 742-750; *abs. in Wasser u. Abwasser*, 9 (1914), No. 2, pp. 50, 51).—From a critical review of the literature on the subject it is concluded that ground water does not originate solely through seepage of precipitation, but in many cases is formed only by the condensation of water vapor. It is pointed out that the transpiration of rainfall by forests often reaches 400 mm. (about 15.7 in.) annually and that this moisture is returned to the soil in the form of vapor and there condensed.

The importance of forests with reference to the water supply, K. E. NEY (*Wasser*, 10 (1914), No. 18, pp. 521-524; *abs. in Wasser u. Abwasser*, 9 (1914), No. 2, p. 51).—The author disagrees with the assumption that the heavy forest-

ing of a region has a directly favorable influence on its water supplies and quotes data to substantiate his conclusion.

Hypochlorite treatment of water supplies, H. A. WHITTAKER (*Pub. Health Rpts.* [U. S.], 30 (1915), No. 9, pp. 608-618, pl. 1, figs. 8).—A small portable plant for the hypochlorite treatment of polluted water supplies is described and illustrated which consists of one mixing and two storage barrels, a mixing apparatus, a solution controlling device, and the necessary valves and connections.

Water and sewage, H. C. MÜLLER ET AL. (*Ber. Agr. Chem. Kontroll u. Vers. Stat. Pflanzenkrank. Prov. Sachsen*, 1913, pp. 15-20; *abs. in Wasser u. Abwasser*, 9 (1914), No. 2, pp. 39-41).—Chemical and biological studies of public and private water supplies and soils and crops injured by sewage from industrial works showed that in country communities ditch water could not be used in place of ground water on account of the turbidity and color caused by brown coal particles. The water for artificial rain irrigation, it is stated, should be as nearly like actual rain water as possible.

Out of 27 samples of drinking water only 13 were unobjectionable, and of the remaining samples 7 were grossly polluted, 2 were doubtful, and 5 were highly impregnated with mineral matter. Three samples of water used for stock were too highly polluted for safe use. Out of 10 samples of dairy water supplies only four were unobjectionable.

Mixing sewage containing salts with ground water samples caused a marked deterioration in the quality of the latter in 3 out of 11 cases. Analyses of samples of brook and pond waters receiving the drainage from potash works showed the contamination to increase with the depth of the water, thus indicating that the safe dilution of such drainage is not always a certainty.

Water from brown coal ditches showed a high salt content, as did also brook water receiving such drainage. The contamination of brook water by the sewage from a dairy and a brewery was evidenced by the development of typical sewage organisms.

Plastic colloidal clay was found to be unsatisfactory for sewage purification purposes.

Report of the state highway commission of Minnesota for 1914 (*Rpt. Highway Com. Minn.*, 1914, pp. 235, pl. 1, figs. 38).—This report includes the history of the Minnesota state road laws, a description of the Koochiching County fire breaks, and tabulated reports of road and bridge operations for each county.

Concrete roads versus macadam, E. H. McALISTER (*Univ. Oreg. Bul.*, n. ser., 10 (1913), No. 5, pp. 16, fig. 1).—It is concluded that concrete is considerably superior to macadam for Oregon highways which must withstand modern traffic. Tests also indicate the value of blends of puzzolanic material and cement.

The design of concrete highway bridges with special reference to standardization (*Engin. and Contract.*, 43 (1915), No. 12, pp. 268-270, figs. 5).—This is a discussion by C. B. McCullough of the various factors influencing the design of concrete highway bridges, particularly standard types. Specific data and diagrams are given showing the effect of stream behavior, loadings, temperature stresses, etc., and illustrating some standard types of the Iowa Highway Commission.

The economic design of culverts for various depths of fills, P. K. SHEIDLER (*Engin. and Contract.*, 43 (1915), No. 13, pp. 288-290, figs. 7).—This article discusses the economic length of road culverts and gives comparative costs of culverts constructed with long and short barrels.

Results of some tests to determine the effect of normal and low temperatures on the strength of cement mortar (*Engin. and Contract.*, 43 (1915), No. 9, pp. 196, 197).—In tests of 1:2 cement and sand briquettes it was found that subjecting the briquettes to freezing temperatures after allowing them to set four days at temperatures above freezing materially reduced their strength. The use of a 5 per cent salt solution in place of water slightly increased the strength after 14 days of setting. Briquettes subjected first to freezing temperatures and then to nonfreezing temperatures apparently regained their original strength.

Use of electricity for irrigation and on the farm, C. H. WILLIAMS (*New York: Nat. Elect. Light Assoc.* [1912], pp. 59, figs. 22).—After a general review of the situation relative to the use of electricity for irrigation pumping and for farm power purposes, the author summarizes by stating that "from the viewpoint of the farmer the introduction of electricity into farm methods reduces the cost of production of farm products. The chief saving is in labor and the ability to apply scientific and systematic methods to the industry. From the central station viewpoint it means an off-peak load, a high kilowatt-hour current consumption, and a satisfied customer."

When the gas engine will not start, E. N. PERCY (*Power*, 41 (1915), No. 9, pp. 299, 300).—Directions are given for systematically following up the trouble when an engine refuses to start, with suggestions for remedying it when located.

Progress in small farm tractors, L. W. ELLIS (*Sci. Amer.*, 112 (1915), No. 14, pp. 306-308, figs. 10).—This article touches briefly upon tendencies in construction, general principles, and the present status of the small tractor industry. "In the face of such evident disagreement as to the eventual type the safest course in buying is to investigate all claims thoroughly and insist that the product shall be past the experimental stage and the firm behind it permanent and substantial."

Report of international competition of motor tillage machines at Chaouat, Tunis, in 1914 (*Compte Rendu du concours International d'Appareils de Labourage à Moteurs à Chaouat. Tunis: Dir. Gén. Agr.*, 1914, pp. 59, pls. 30; *abs. in Internat. Inst. Agr.* [Rome], *Mo. Bul. Agr. Intel. and Plant Diseases*, 5 (1914), No. 11, pp. 1485-1487).—This article has been previously noted (*E. S. R.*, 32, p. 189).

Tests of two milking machines, B. MARTINY and P. VIETH (*Arb. Deut. Landw. Gesell.*, No. 271 (1914), pp. 41, figs. 6).—After thorough testing the judges reported more or less favorably in both cases.

A shearing shed, sheep yards, and dip, J. S. MCFADZEAN (*Jour. Dept. Agr. Victoria*, 12 (1914), No. 10, pp. 601-605, figs. 2).—Plans are shown of a shearing shed, sheep yards, and dip, which it is claimed have given complete satisfaction.

A shearing shed for small flocks, J. W. MATHEWS (*Agr. Gaz. N. S. Wales*, 26 (1915), No. 1, pp. 5-10, figs. 6).—A sheep-shearing shed to provide accommodation for the shearing of 6,000 sheep is illustrated in plan, section, and detail.

Fences and fencing (*Dept. Agr. N. S. Wales, Farmers' Bul.* 74 (1914), pp. 32, figs. 25).—This bulletin reports a number of experiments with different types of fences and gates, giving specifications for the experimental fences and describing them in detail.

In experiments with reference to the use of posts and droppers, several different fences were constructed which are classified in two sections as follows: "In section 1, which deals with the number of posts necessary for efficiency, pattern A has the posts 8 ft. 3 in. apart (640 per mile); pattern B has the posts 16 ft. 6 in. apart (320 per mile), 1 dropper between the posts; pattern C has the posts 22 ft. apart (240 per mile), 2 droppers between the posts; pattern D has the posts 33 ft. apart (160 per mile), 3 droppers between the posts. In

section 2, which aims at determining the most suitable dropper to use, the posts are 33 ft. apart with 3 droppers between the posts. Pattern D has wooden droppers, i. e., rigid droppers; pattern E has the plain ('Anchor') No. 6 B. W. G. wire droppers; pattern F has the crimped ('Cyclone') No. 6 B. W. G. wire droppers."

It is stated that after seven or eight years' service the fence consisting of posts only was the most efficient of all, but the most costly, and that efficiency decreased as the number of posts per mile decreased. The fences in which the posts were 33 ft. apart proved too weak for big stock, especially when the strain imposed by wind and weather was considered. The fences with three or more posts to the chain proved satisfactory.

The most efficient dropper was found to be the wooden type, but it was also the most costly. The next best was the crimped dropper, and the least efficient was the straight wire dropper.

Sections are included describing and illustrating different types of gates and gateways and a cheap sheep and cattle proof fence, and instructions are given for squaring a gatepost.

In experiments with concrete fence posts made of a mixture of 1 part cement, $2\frac{1}{2}$ parts sand, and 5 parts gravel and reinforced with four pieces of No. 6 wire, it was found that concrete is a suitable material for fence posts in the climate of New South Wales. It is estimated that where suitable gravel and sand are easily obtained, concrete fence posts can be made for about 25 cts. each. Concrete gateposts are said to have decided advantages over wooden ones, especially in that they do not require painting to keep them in good order.

A final section by R. H. Gennys gives hints on fencing for settlers.

Country plumbing practice, W. HUTTON (*New York: David Williams Co., 1914, pp. 310, figs. 229*).—It is the purpose of this book "to offer some assistance in designing and installing the various appliances necessary for the supply of water by gravity or mechanical power and for the disposal of sewage and kitchen wastes by the biological process. The maintenance of the appliances in proper repair has also received consideration, and it has been the intention throughout to arrange the subjects treated in a manner which would appeal to the men who are most likely to require assistance—the plumbers who are called upon to install or repair any of the hundred and one appliances which the requirements of local conditions may entail."

Owing to the smaller number of fixtures in country than in city buildings, it is stated that the plumbing may be made much more simple. "In the design of plumbing construction in various types of buildings these conditions have received full consideration and the simplification of the systems of waste and vent lines has been advised wherever possible."

In addition to the strictly sanitary engineering features, the author has taken up at some length the more important mechanical and structural features involved in obtaining running water, such as pumping, power for pumping, well digging, the operation of special types of water-supply systems, and plumbing installations. The following chapters are included: Engines used for water-supply systems; mechanical details of gasoline engines; sources of electric current, cooling, governing, and repair of engines; setting gasoline engines and pumps; hot air engines, windmills, and electric motors; steam driven pumps; hydraulic rams; selection of a water supply, determining quantity and quality, filtration, relative corrosion of pipes; water supply from wells and springs, methods of raising water; distribution of water supply to buildings; water supply by air pressure, fire protection, sprinklers; sewage disposal from isolated buildings, various methods of liquefaction, filtration and disposal; methods of

laying tile and iron drains from house to sewer or outfall at septic tank; collection and storage of rain water; covering sink drip boards with sheet metal; roof connections, bubbling fountains, plumbing tests; structural features of country plumbing systems; examples of work in country schools, office buildings, stations, and other public buildings; and installing plumbing in old buildings.

Farm sanitation, C. H. WRIGHT (*Jour. Dept. Agr. Victoria, 11 (1913), Nos. 4, pp. 215-220, figs. 11; 5, pp. 306-311, figs. 12; 7, pp. 410-413, figs. 4; 12 (1914), No. 4, pp. 228-230, figs. 3*).—Methods of arranging plumbing for the disposal of sewage from farmhouses are described and illustrated and the biological action in septic tanks and filters is discussed. The author advocates the use of a house sewer trap, on the ground that the seals in fixture traps may be destroyed at times, thus permitting the escape of sewer gas.

Methods of sewage disposal for country homes, O. M. BALL and H. CASSIDAY (*Agr. and Mech. Col. Tex. [Ext. Ser. Bul. 1] (1914), pp. 3-10, figs. 3*).—This bulletin gives the usual description of the process of sewage disposal by means of sewage tanks and filters and illustrates two types of septic tank. The Kentucky sanitary privy is also described and illustrated. In opposition to the usual statement, it is stated that "the septic tank, when properly constructed and not overloaded, will work automatically and will deliver an effluent about 80 per cent pure."

Sewage disposal in the country (*Bul. Vt. Bd. Health, 15 (1915), No. 3, pp. 33-45, pls. 2, figs. 2*).—It is the purpose of this paper to describe simple methods for disposing of farm sewage, the usual discussion of the process of sewage disposal by sewage tanks and filters being included.

It is stated that a common misunderstanding exists regarding the action of a septic tank. "It is thought that this tank completely purifies the sewage and that the overflow from such a tank can be freely discharged into a stream used for drinking purposes. Such, however, is far from being the true condition, as the work of this tank is a preliminary process, and must be followed up by other processes if full purification of the sewage is required."

Investigations on the disposal of canning factory wastes at Washington, Illinois, D. ENGLIS (*Univ. Ill. Bul., 11 (1914), No. 38, pp. 339-373, figs. 12*).—A general discussion of the subject of the disposal of canning factory wastes and a brief review of the work of others bearing on the subject is followed by a report of experiments on the purification and disposal of corn and pea canning wastes.

Such crude liquid wastes are high in color, carry more or less suspended matter when fresh, have an odor characteristic of the vegetable being canned, and when in a putrescible condition have a very foul odor. The corn wastes putresce less rapidly than do the pea wastes.

It was found that the bulk of the coarser solids in both wastes may be removed by a suitably designed screen chamber. Plain settling basins remove a comparatively small quantity of solid matter by sedimentation. "Generally speaking, it would be better to make no effort to settle the solids after they have passed the screens, but rather pass them through a skimming chamber or through fine screens before the liquid enters the dosing chamber or reservoir. The entire contents of the dosing chamber or reservoir, including such sludge as may settle, can best be disposed of on filters or broad irrigation beds. Experience during the experiments would indicate that the storage reservoir or dosing chamber should be of sufficient capacity to cover a single filter unit to a depth of about 3 in., and this quantity should be applied within an hour."

For actual working conditions it is believed inadvisable to apply sewage at a rate greater than 40,000 gal. per acre per day. "The cultivation of the beds is an important feature in securing success, and this cultivation can best be

carried out by harrowing. . . . The use of contact beds does not appear promising, whereas sand beds may be used to great advantage where sand is available in sufficient quantity and at sufficiently low cost."

It is concluded that the problem of cannery waste disposal in this particular instance has been adequately solved by the use of broad irrigation beds. "On the other hand, such methods must be regarded as of special applicability, dependent upon the availability of suitable soil, and it must be emphasized that no specific problem of cannery waste can be properly solved without taking due cognizance of local conditions."

RURAL ECONOMICS.

Agricultural cooperation and rural credit in Europe (*U. S. Senate, 63. Cong., 2. Sess., Doc. 261 (1914), pts. 1, pp. 29; 2, pp. 15*).—Part 1 of this report is a summary and digest of the information and evidence secured by the American Commission (E. S. R., 28, p. 301), and describes the general agricultural conditions in Europe, long, short-term, and cooperative credit, cooperation in production and distribution, and the organization of agriculture and rural life. Among the conclusions of the commission are the following:

"One of the most pressing economic needs of American agriculture is the opportunity to secure, on better terms than at present prevail, the necessary capital, and, consequently, the necessary credit demanded by modern conditions of farming. In order that there may be a uniform and nation-wide system of long-term credit, it would seem wise to secure the enactment of a federal law permitting the organization of farm-land banks, either on the joint-stock or the cooperative plan, authorized to issue long-time bonds secured by farm mortgages, required to do business on a narrow margin of profit, to allow payment of principal on the amortization plan, and carefully and fully supervised by the federal government. There is no objection whatever to the enactment of proper legislation by the different States for this same purpose.

"In case the existing system of banks—national, state, savings, and private—is not able or not disposed to grant farmers increased and more liberal facilities for procuring short-time loans, there should be enacted state laws permitting the organization of cooperative credit associations by means of which the farmers of a given community may be enabled to meet their own needs for short-term or personal credit.

"Every encouragement should be given the movement for organizing other forms of cooperative endeavor among farmers. This movement should proceed cautiously but rapidly. The main reliance of the American farmers in meeting economic disadvantages and handicaps must be their own intelligence and their capacity for united action. . . .

"In order to give national scope and direction to the campaign for rural community building, there should be organized a National Committee on Rural Federation, whose task would be to hold national conferences on rural progress, to seek to unify or correlate the many important and useful agencies already at work for rural advancement, and to give direction to the ultimate welding together, in one great forward-looking movement, of all the forces designed to insure on American soil better farm practice, better farm business, and better farm life."

Part 2 is a report of the minority members of the American Commission, pointing out that the difference in economic, social, and religious conditions among farmers in European countries prevent the adoption of the European system of agricultural credit in the United States. The minority members outline a system whereby it is proposed that the farmers cooperate with the stock-

holders of banks in rural communities in the organization in their respective localities of small unit land-mortgage associations. Each association would be organized upon the share capital plan, cooperative or noncooperative as might be desired. It is to become affiliated with and have close interrelationship with the rural bank, which may be owned by some of the same shareholders, in that it may have its office with the affiliated bank and be officered, managed, and directed by some of the same men, to which could be added other desirable farmer directors, if such rural banks are not already dominated by that interest. (See also previous notes E. S. R., 30, p. 792; 31, pp. 293, 389.)

Agricultural cooperation and rural credit in Europe, III (*U. S. Senate, 63. Cong., 1. Sess., Doc. 214, pt. 3 (1913), pp. 95*).—Part three of the report noted above contains a brief statement submitted to the American commission by the different States of the United States and Provinces of Canada regarding their agricultural needs, especially as they relate to the furnishing of proper credit facilities to the farmers. Rural credit laws of Texas, Wisconsin, New York, and Massachusetts are included, together with a description of the work of the Jewish agricultural aid societies.

Report of the Irish Agricultural Organization Society, Limited, 1914 (*Rpt. Irish Agr. Organ. Soc., 1914, pp. 163*).—This report reviews the work for the year and points out methods that may be used to meet the exigencies caused by the war. The report is mainly devoted to statistical tables indicating the extent of the business transacted during the year.

Social and economic survey of a community in the Red River Valley, L. D. H. WELD (*Univ. Minn. Current Problems, No. 4 (1915), pp. IV+86, figs. 32*).—The author gives a historical sketch of the community and describes the general farming conditions, the methods of living on the farm and in the village, the methods of marketing farm products, and the stores and industries in the village. He found that the community was dependent mainly upon grain crops which meant a more or less fluctuating income and a partial exhaustion of the soil. These facts had an important bearing not only on the economic well-being and standard of living of the farmers, but also upon the social activities of the community.

He points out that the long distances between farmhouses, the mixture of nationalities and religions, the cold winters, and the long hours of work, all stand in the way of the development of social intercourse among farmers. The flour mill has an important and beneficial influence on the local wheat market, and the local elevators offer a satisfactory market for grains, yet some saving might be obtained through a cooperative company which could purchase supplies in carload lots for its farmer members. Too much butter is made on the farm and not enough cream is hauled to the creamery. Eggs are still traded at the store with little attention to production, grading, etc. The number of stores in the village is much larger than necessary to supply efficiently the population of the section. The mail-order business amounts to only about 3 per cent of the total business of those stores which are open to this sort of competition. The social life of the village is very pleasant and the people form close friendships, yet they seem to be divided into well-defined groups and lack contact with the outside world. Their standard of living is high and their homes comfortable and attractive. The cost of living is considered lower than that of larger cities.

The study of a rural parish, R. A. FELTON (*New York: Bd. Home Missions Presbyterian Church, 1915, pp. [232]*).—This book contains directions and forms for making and summarizing a rural survey, and a brief bibliography relating to special features of country life.

Mortality statistics, 1913 (*Bur. of the Census [U. S.], Mortality Statis., 14 (1913), pp. 631, figs. 7*).—Among the statistics contained in this report are the following relating to the rural population: Total number of deaths, general death rate, death rate per 100,000 persons from specific causes for the registration area of the United States and for individual States within that area, and total number of deaths by causes for rural parts of registration States.

National subsistence and agricultural colonization, H. KRANOLD (*Massen-ernährung Agrarpolitik Kolonisation. Munich: G. C. Steinicke, 1914, pp. 95*).—This report discusses changes in German agriculture relative to its making the nation self-sustaining, and indicates the extent and the control of the national deficit in agricultural products and its social and hygienic effect upon the people. A number of statistical tables are included showing changes that have taken place.

[**Agriculture in Norway**] (*Statis. Aarbok Konger. Norge, 34 (1914), pp. 26-35*).—These pages continue statistical data previously noted (*E. S. R., 31, p. 192*), to include 1913.

Agriculture in Serbia, F. O. WALDMANN (*Fühling's Landw. Ztg., 64 (1915), No. 2, pp. 55-60*).—The author briefly summarizes the agricultural conditions in Serbia by describing the climatic conditions, area and kinds of crops grown, and types and number of live stock.

Estimates of area and yield of principal crops in India, 1913-14 (*Dept. Statis. India, Est. Area and Yield Princ. Crops India, 1913-14, pp. 25, pl. 1*).—This report gives for 1913-14 the area and total and average yields by Provinces for the principal crops, and explains the methods of making estimates and collecting statistics. Comparative data are given for earlier years.

Pineapple-canning industry of the world, J. A. SHRIVER (*U. S. Dept. Com., Bur. Foreign and Dom. Com., Spec. Agents Ser., No. 91 (1915), pp. 43*).—This report describes the extent of this industry, methods employed in conducting canneries, the labor problems, and factory systems.

Monthly crop report (*U. S. Dept. Agr., Mo. Crop. Rpt., 1 (1915), No. 3, pp. 12, figs. 6*).—This number gives the usual monthly estimates of the acreage, condition, and yield of the more important agricultural crops, the farm prices of important products, and the range of prices at important markets, with miscellaneous data, including charts showing the monthly variation in live-stock prices.

An inquiry as to the use of corn for silage shows that approximately 8 per cent of the corn acreage last year was cut for silos, 11 per cent cut green for feed, and 81 per cent matured for grain. Detailed percentages and acreages are shown by States.

An inquiry as to the extent of this year's reduction in the use of commercial fertilizers for cotton, as indicated by the sales of fertilizer inspection tags to June 25, 1915, compared with the sales for the last year to that date, shows that there was a reduction of 25 per cent for North Carolina, 45 for South Carolina, 44 for Georgia, 32 for Florida, about 50 for Alabama, 26 for Mississippi, 19 for Louisiana, and 70 for Arkansas.

It is pointed out that the reduction in the absolute quantity of commercial fertilizers used does not measure the full extent of the loss in the productive powers of the plant, since the quality of the fertilizers sold is much inferior to last year's supply because of the lack of available supplies of potash. It appears, however, that the southern farmers have exerted themselves to a hitherto unknown extent in the utilization of home-produced composts and natural manures.

Farmers' market bulletin (*North Carolina Sta., Farmers' Market Buls. 1 (1914), No. 3, pp. 15; 2 (1915), No. 3, pp. 16*).—Suggestions are given on mar-

keting apples and butter, with a list of the butter and egg dealers who desire quotations on North Carolina butter. The second bulletin criticizes the methods used in marketing North Carolina corn and cotton, and discusses the feasibility of county, state, and national cooperation in grading cotton. Both bulletins contain the usual list of products which farmers have for sale.

AGRICULTURAL EDUCATION.

First annual report on vocational education in Indiana, W. F. BOOK (*Ann. Rpt. Vocational Ed. Ind., 1 (1914), pp. 169-230, figs. 4*).—This report deals with the vocational education law of Indiana, types of vocational schools to be established, progress made in vocational instruction, instruction in agriculture, domestic science, and industrial arts in the regular schools, work of county agents of agriculture, and agricultural clubs, and school and home gardening work.

The state board requires that at least two regular recitation periods a week in the seventh and eighth grades be devoted to the study of agriculture, industrial arts, or domestic science, and that township, town, and city high schools offer at least one year's work of five recitations a week in domestic science and a full year's work in agriculture or industrial arts. Last year 39,810 students in Indiana studied elementary agriculture and 46,985 domestic science. The amount of time devoted to instruction in these subjects ranged from 50 to 80 minutes a week in the grades and from 90 to 450 minutes in the high school. Instruction in agriculture was given by 5,928 teachers, of whom 747 had studied agriculture, and instruction in domestic science by 4,575 teachers, of whom 610 had studied the subject for from 6 to 18 weeks.

Thirty-four township and district supervisors of agriculture were employed last year in 12 counties and 59 township and district supervisors of domestic science in 16 counties. The agricultural extension department of Purdue University has contributed the services of 3 men to assist the state superintendent of public instruction in supervising agricultural instruction in the regular schools; 27 county agents prepared special outlines for work in agriculture in the schools, issued bulletins on helps for teachers, gave instruction in agriculture at 134 township and county institutes, and visited 935 schools, in some instances directing the field and laboratory exercises and during the summer months supervising the club projects; and 2,500 boys and girls were enrolled in club work during the summer of 1914, and a similar number in home projects in corn and potato growing, poultry raising, and gardening and canning.

State-aided vocational agricultural education in 1914 (*Ann. Rpt. Bd. Ed. [Mass.], 78 (1913-14), pp. 274-312; Bul. Bd. Ed. Mass., No. 40 (1915), pp. 40*).—This is a detailed report on the organization and activities of the vocational agricultural schools and departments in Massachusetts, including statistical tables showing reimbursements as to salaries and tuition, the vocational agricultural instructor's preliminary survey for home projects prior to approval of admission of pupils, examples of the income of pupils from farm work during attendance at school, etc.

Agriculture in the New York state high schools, L. S. HAWKINS (*Cornell Countryman, 12 (1915), No. 7, pp. 559-562, figs. 3*).—The author gives a general description of the agricultural work extending through 4 years in the 48 high schools in New York receiving state aid for agriculture.

[Agricultural education in the Philippines] (*Philippine Craftsman, 2 (1914), No. 8, pp. 535-644, figs. 83*).—This issue is devoted to a survey of agricultural education in the Philippines given in the following special articles: Spain's Contribution to Philippine Agriculture, by A. Craig; What the Philippine Public Schools are Doing in Agriculture; School and Home Gardening, by N. H.

Foreman; The Villar Settlement Farm School, by W. J. Cushman; The Lum-bayao Settlement Farm School, by G. C. Kindley; The Mailag Agricultural School, by J. C. Scott; The Indang Farm School, by J. A. Cocannouer; The Central Luzon Agricultural School, by K. O. Moe; Food Campaigns Through the Medium of the Philippine Public Schools, by N. H. Foreman; The College of Agriculture, by E. B. Copeland; and Notes on the Work of the Bureau of Agriculture, by W. K. Bachelder.

A new year in agricultural instruction (*Agr. Gaz. Canada*, 2 (1915), No. 1, pp. 28-51, figs. 11).—An account is given of the organization and development of agricultural instruction in Prince Edward Island, together with notes of work planned for the coming year in other Canadian Provinces.

Elementary agricultural instruction (*Agr. Gaz. Canada*, 2 (1915), No. 2, pp. 151-170, figs. 7).—The plans and policies of organization of elementary agricultural instruction in the schools of Prince Edward Island, Nova Scotia, New Brunswick, Quebec, Ontario, Manitoba, Saskatchewan, Alberta, and British Columbia, are described.

Vocational education in Europe, E. G. COOLEY (*Chicago: Com. Club Chicago*, 1915, vol. 2, pp. 177, pls. 8).—This is a report based on personal visits and studies by the author on the historical development and present status of agricultural instruction in Denmark, Ireland, Holland, and Germany, schools of country housekeeping in these countries, vocational guidance in London, and welfare of the working youth in Germany. A résumé of the report of the Swedish royal commission on elementary technical instruction is included.

Regulations for grants in aid of agricultural education and research in England and Wales, 1915-16 (*London: Bd. Agr. and Fisheries*, 1915, pp. 25).—This pamphlet deals with the conditions under which grants under the Development Act are awarded. See also a previous note (E. S. R., 31, p. 794). A letter authorizing the payment of grants from the Development Fund for agricultural research and a memorandum on agricultural education in connection with farm schools and farm institutes are appended.

Agricultural training for women in Holland, S. R. VON RAMULT (*Land u. Forstw. Unterrichts Ztg.*, 28 (1914), No. 3-4, pp. 225-233).—This account is similar to but more extensive than the one previously noted (E. S. R., 32, p. 92).

Education for efficiency, E. DAVENPORT (*Boston: D. C. Heath & Co., rev. ed.*, 1914, pp. V+196).—In this revision of this text (E. S. R., 22, p. 593) the author includes in the preface a series of propositions on vocational education published in a recent report of the Illinois Educational Commission. He also substitutes for the proposed high-school course in the first edition a more modern course from the report just mentioned, and for the discussion of "agricultural development and public investment" a chapter on The Meaning of Agriculture, including its importance and evolution, the balance of trade, the ultimate condition, the need for a rural credit system, the meaning of land tenure, and the people of the farm.

The proper preparation and equipment, academic and professional, of teachers in schools of agriculture, C. G. MAPHIS ([*University, Va.: Author*], 1915, pp. 13).—The author discusses the need of properly trained agricultural teachers and their qualifications, and refers to the policy of teacher training for secondary schools in Germany and to the joint recommendations of the Committee of Seventeen on the professional preparation of high-school teachers. In his opinion teacher training involves broad academic knowledge as a basis, leadership, professional knowledge, and specialized knowledge of the particular subject to be taught. Academic training of teachers in the secondary schools of agriculture should not be less than four years of standard college

work, the group system should prevail, and several groups of subjects allied with agriculture should be extensively studied. English should not be neglected and a sufficient number of other courses of general culture should be pursued. The theoretical and practical professional training should not be less than specified and in addition at least a year in practical experience on a farm should be insisted upon.

School credit for home work, L. R. ALDERMAN (*Boston: Houghton Mifflin Co., 1915, pp. X+181, pls. 8*).—The author narrates the working out of the school credit for home work idea, including illustrative home credit plans in elementary and high schools. An appendix contains the essential features of a bulletin of the Kansas State Agricultural College entitled, *School Credit for Home Work*, and a brief report by the California Teachers' Association on credit for work done outside of school.

Teaching agriculture in rural and graded schools, E. C. BISHOP, R. K. FARRAR, and M. H. HOFFMAN (*Off. Pub. Iowa State Col. Agr., 13 (1914), No. 20, pp. 175, figs. 30*).—In this revision (*E. S. R., 31, p. 298*) references to literature, etc., have been brought up to date and poultry studies added.

Lessons in elementary agriculture for Alabama schools, E. A. MILLER (*U. S. Dept. Agr. Bul. 258 (1915), pp. 36*).—This series of lessons adapted to Alabama conditions has been prepared for the use of rural school teachers. A monthly sequence plan is followed and practical and correlation exercises are suggested in connection with each lesson. References to bulletins of the Alabama Polytechnic Institute and to Farmers' Bulletins of this Department are also included to supplement the text-book material and provide a reading course for the teacher.

Pre-vocational agricultural courses of the public schools of Indiana (*Dept. Pub. Instr. [Ind.], Ed. Pubs., Bul. 15 (1915), pp. 223*).—Minimum courses in soils, crops, animal husbandry, dairying, poultry, and horticulture, prepared by the state board of education, are outlined, in seasonal sequence, for the seventh and eighth grades 1915-16 and 1916-17, and for high schools, the latter including also vegetable gardening, farm mechanics, civics, and history. Lists of agricultural reference books and of apparatus and equipment are included.

Elementary principles of agriculture, A. M. FERGUSON and L. L. LEWIS (*Chicago: Ferguson Publishing Co., 4. ed., 1913, pp. X+390, pls. 7, figs. 232*).—The fourth revised edition of this text contains as new matter, 10 chapters on crops and an appendix giving the annual rainfall in the United States for the years 1898-1907, inclusive (*E. S. R., 29, p. 193*).

Practical lessons in agriculture, L. S. IVINS and F. A. MERRILL (*New York: American Book Co., 1915, pp. VI+223, figs. 96*).—This is a text-book and laboratory manual for use from the seventh to the tenth grades. The lessons, most of which are laboratory or field exercises and are arranged in seasonal sequence, treat of sources of food, clothing, and shelter; the atmosphere; seeds; soils; fertilizers; plant production; insects; weeds; field crops; vegetables; fruits; school and landscape gardening; farm forestry; school grounds; birds; feeding, housing, and care of farm animals; selection of meat animals; milk and its products; poultry; packing and marketing products; farm buildings and machinery; farm drainage; good roads; a census of neighborhood farm crops, animals, and weeds; distribution of cotton, corn, hogs, and cattle in the United States; farm cooperation, etc.

A study of Indian corn (*Zea mays*), J. C. RUNDLES (*Philippine Agr. and Forester, 3 (1915), Nos. 9-10, pp. 228-243, fig. 1*).—The author describes the method of studying Indian corn in the Philippine College of Agriculture,

discusses the advisability of corn standards, and outlines and explains the score card in use.

Poultry keeping, H. R. LEWIS (*Philadelphia and London: J. B. Lippincott Co., 1915, pp. XVIII+365, pl. 1, figs. 182*).—This text for rural and graded schools, which with slight adaptations may be used in high schools, consists of an introductory discussion of different grades and methods of instruction in poultry husbandry and a treatise dealing with the different breeds, hatching and rearing, housing and feeding, products, health, diseases and enemies, and management of poultry. Each chapter is followed by laboratory exercises, a list of review questions, and references to literature. Lists of reference books and of colleges and stations giving attention to poultry problems, a plan and rules for boys' and girls' poultry contests, score cards, and data on the composition and digestibility of common feeding stuffs, etc., are appended.

Poultry keeping project study outline (*Bul. Bd. Ed. Mass., No. 36 (1914), pp. 139*).—This poultry keeping project outline consists of questions and references for producing and disposing of live poultry, eggs, turkeys, ducks, and geese.

Housekeeping, ALICE M. FULLER (*Manila: Bur. Ed., 1914, pp. 298, pls. 3, figs. 59*).—This text-book for girls in the public intermediate schools (grades 5 and 6) of the Philippines consists of reading lessons and practical exercises in housekeeping and cooking, sewing and textiles, hygiene and home sanitation, and ethics.

Agricultural economics, E. C. SEDLMAYR (*Land u. Forstiv. Unterrichts Ztg., 28 (1914), No. 3-4, pp. 203-219*).—The author gives an outline for instruction in agricultural economics, and discusses the relations of agricultural economics to agricultural production and to political economy, as well as the use of monographs, statistics, and farm experiments in the promotion of instruction in agricultural economics.

Observations on legal instruction in secondary agricultural schools, F. A. SCHOLZ (*Land u. Forstiv. Unterrichts Ztg., 28 (1914), No. 3-4, pp. 220-224*).—Observations are made on instruction in constitutional, civil, and administrative law, including its relation to agriculture, in the secondary agricultural schools in Austria, all of which devote 2 hours a week to this subject in the third year, and 2 hours a week to political economy in the second year.

Outline of nature-study, G. H. TRAFTON (*Nature-Study Rev., 11 (1915), No. 3, pp. 94-169, figs. 2*).—The author gives a detailed outline of the nature-study course, arranged according to seasons, in use in the elementary school of the State Normal School at Mankato, Minn., together with a study of the aims, available materials, and methods of teaching nature study and its relation to other subjects.

Course III. Home gardening, E. C. BISHOP and G. R. BLISS (*Iowa State Col. Agr. Ext. Circ. 17 (1912), pp. 3-16, figs. 4*).—General regulations and directions are given for conducting the work of the individual home garden.

Yard and garden contests, C. L. FITCH (*Iowa State Col. Agr. Ext. Bul. 32 (1915), pp. 16, figs. 12*).—This is a description of the methods employed by a civic organization in the improvement of gardens and yards in Davenport, Iowa.

Suggestions for boys' acre corn club contest, P. C. TAFF (*Iowa State Col. Agr. Ext. Dept., Junior Circ. 28 (1915), pp. 15, figs. 9*).—Suggestions are given for selecting, testing, planting, and cultivating corn.

School gardens, 1915, edited by R. L. TEMPLIN (*Cleveland, Ohio: The Children's Flower Mission, 1915, pp. 48, figs. 31*).—Information and suggestions are given on planning and conducting school and home garden and junior clean-up work, and annual exhibitions.

School gardening and school fairs (*Agr. Gaz. Canada*, 2 (1915), No. 1, pp. 52-61, figs. 2).—Accounts are given of the present status of school gardening and school fairs in Nova Scotia, Quebec, Ontario, Manitoba, Saskatchewan, and Alberta.

School-ground improvements, N. H. FOREMAN (*Manila: Bur. Ed.*, 1914, pp. 56, figs. 4).—A 4-weeks' course of 13 lessons is outlined for teachers of all grades in the Philippines for the purpose of giving them instruction in improving the school grounds with student labor. Directions are given for presenting the course at division normal institutes.

School and home gardening, N. H. FOREMAN (*Manila: Bur. Ed.*, 1914, pp. 56, figs. 2).—This is an outline of a 4-weeks' course in school and home gardening for teachers of elementary grades in the Philippines, together with the method of presentation of the course at division normal institutes.

Home gardens, field crops, and home canning for boys' and girls' club work, O. H. BENSON (*Ann. Rpt. Missouri Bd. Agr.*, 46 (1913), pp. 286-295, figs. 2).—The author discusses essentials, objects, and evidences of good club work, school credit, leadership, relations, projects, prizes and premiums, follow-up work, and club work as related to markets and consumers.

Boys' agricultural clubs, W. H. KENDRICK (*W. Va. Univ., Agr. Ext. Dept. Circ.* 2 (1915), p. 15, figs. 11).—Instructions are given for organizing boys' and girls' corn, pig, potato, and poultry club work.

Annual report of the School Garden, Association of America (*Ann. Rpt. School Gard. Assoc. America*, 4 (1914), pp. 30, figs. 19).—This report contains, among other data, a list of books on home canning, domestic science, poultry, and birds of interest to city people, plans of a model garden, and excerpts from addresses and papers presented at the 1914 annual meeting.

MISCELLANEOUS.

Twenty-first Annual Report of Montana Station, 1914 (*Montana Sta. Rpt.* 1914, pp. 383-408).—This contains the organization list, a financial statement for the fiscal year ended June 30, 1914, a report of the director on the work and publications of the station, and a summary of meteorological observations for 1914. The experimental work reported is for the most part abstracted elsewhere in this issue.

Annual Report of Porto Rico Station, 1914 (*Porto Rico Sta. Rpt.* 1914, pp. 35, pls. 3).—This contains the organization list, a summary by the special agent in charge as to the investigations conducted at the station during the year, and reports of the chemist and assistant chemist, horticulturist, assistant horticulturist, plant pathologist, and entomologist abstracted elsewhere in this issue.

Annual Report of South Dakota Station, 1914 (*South Dakota Sta. Rpt.* 1914, pp. 26).—This contains a report by the director on the organization, work, and publications of the station, a list of exchanges, a financial statement for the fiscal year ended June 30, 1914, and departmental reports.

General review [of the Fourth Scientific Congress], E. POIRIER (*4. Cong. Cient. [Santiago de Chile], 1908-9, Reseña Gen. [pub. 1915], pp. 304, pls. 4, figs. 60*).—This is a general review of the Fourth Scientific Congress (First Pan-American Scientific Congress), held at Santiago, Chile, December 25, 1908, to January 5, 1909, which has been previously noted (*E. S. R.*, 20, pp. 608, 695).

NOTES.

Illinois University and Station.—Plans are completed for the erection of a special genetics building of somewhat temporary construction. It will be a one story brick structure, 40 by 100 feet and will provide, besides three offices, class rooms and laboratory accommodations for 50 students at a time in undergraduate instruction and also separate laboratories for graduate and experiment station work.

Donald McIntosh, professor of veterinary science since 1886, died at Portland, Me., September 5.

Maryland College and Station.—A. C. Stanton has been appointed instructor in the manufacture of dairy products in the college and assistant in dairy investigations in the station, beginning September 1.

Nebraska University and Station.—P. B. Barker has resigned as professor of instructional agronomy and associate agronomist to become associate professor of farm crops in the extension service of the University of Missouri, beginning September 1.

North Dakota College and Station.—The board of regents provided by the recent legislature to take charge of all the higher educational institutions in the State, including the station and the substations, has been appointed by the governor with the consent of the senate as follows: L. F. Crawford president, J. A. Power, Frank White, J. D. Taylor, and Emil Scow. The new board assumed control July 1.

Oregon College.—A system of farm surveys to determine factors contributing to success or failure in Oregon farming is being conducted by H. F. Keyes under a cooperative arrangement between the extension division of the college and the Office of Farm Management of the U. S. Department of Agriculture.

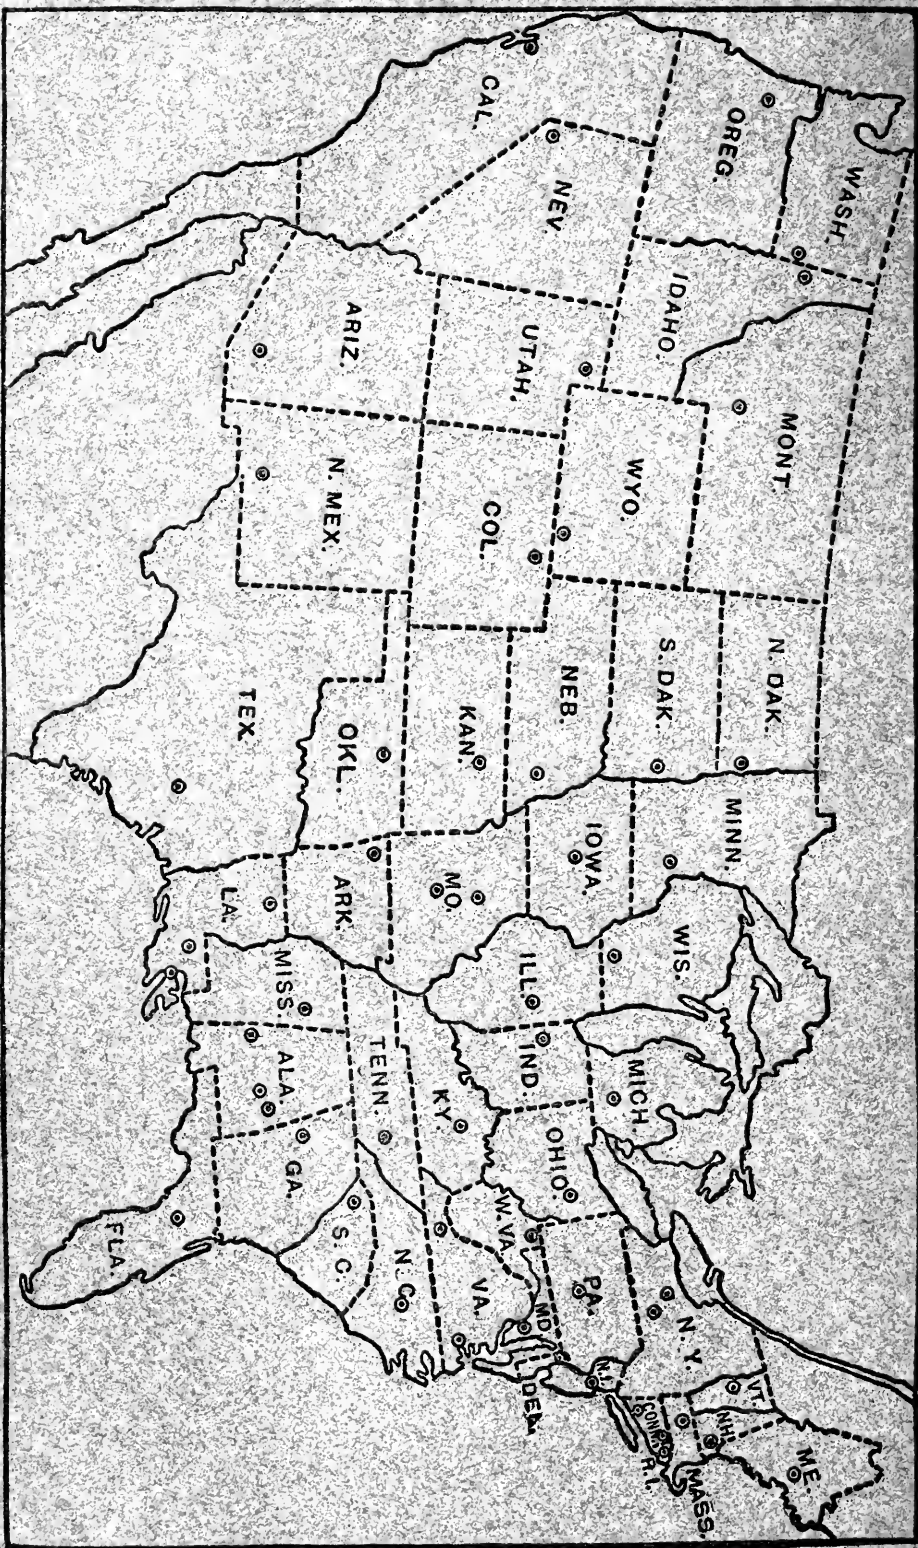

Texas College and Station.—The increasing popular interest in the station is indicated by the material increases in appropriations during the past few years. Six years ago there was no state appropriation for the main station and but \$5,000 per annum with which to operate two substations. For the next two years the appropriation was \$25,000 to operate ten substations. Four years ago it was increased to \$55,000 per annum; two years ago to \$87,500; and the present legislature granted \$140,582.50 for the first year and \$135,000 for the second year of the biennium. This appropriation has been approved by the governor without curtailment. Steps have also been taken for the erection of a station building, to be paid for from the feed-control-service revenue.

Other appropriations include a stock-judging building to cost \$40,000; \$2,000 to remodel the dairy barn for horses and beef cattle; \$1,500 each for a sheep and hog barn; \$21,000 for the purchase of live stock and the maintenance of the animal husbandry department; and \$12,000 for a new dairy barn. A substation is to be established in west Texas for studies in goat breeding.

Bailey O. Bethell, D. V. M. (Ohio State University, 1915), has been appointed instructor in veterinary science, beginning July 1.

Wyoming Station.—Considerable new laboratory equipment has been installed in the various departments, especially those of engineering chemistry, agronomy, and wool investigations. P. T. Meyers has been appointed assistant agronomist, beginning September 1.

CONTENTS OF VOL XXXIII, NO. 7.

Editorial notes:	Page.
The element of chance in agricultural experimentation and investigation.	601
Recent work in agricultural science.....	609
Notes.....	699

SUBJECT LIST OF ABSTRACTS.

AGRICULTURAL CHEMISTRY—AGROTECHNY.

The acids and colloids of humus, Fischer.....	609
A new reaction for clay, Rathgen.....	610
Some methods for the determination of alkali in soils, Hare.....	610
Comparative investigations of Thomas slag powders, Holle.....	610
Methods of bacterial analyses of air, Ruehle.....	610
Differentiation of yeast with aid of agglutinins, Lichtenstein-Rosenblat.....	611
Picric acid as a titrametric standard, Pfeiffer.....	611
The titrametric estimation of free sulphurous acid, Kedesdy.....	611
A new simple method for determining free sulphurous acid, Sander.....	611
Cause of loss of sulphuric anhydrid and chlorin by incinerating, O'Sullivan...	611
Volumetric determination of copper, Zuccari.....	612
Detection of vegetable fats in animal fats, Klostermann.....	612
Separation of sterins from fats with digitonin, Berg and Angerhausen.....	612
Methods for the quantitative estimation of mannit, Smit.....	612
Determination of amino acid and polypeptid nitrogen, Adler.....	613
The presence of citric acid in natural wines, Blarez, Denigés, and Gayon.....	613
Analysis of milk, Meillère.....	613
Specific weight of milk serum in detection of water adulteration, Herramhof..	613
Lime-sulphur sprays, their composition and analysis, Ramsay.....	613
Manufacturing dicyanamid from lime nitrogen, Grube and Nitsche.....	614
Formation of furfural from wood during the steaming process, Heuser.....	614
Chemical utilization of southern pine waste, Whitaker and Bates.....	615
The possibilities of hardwood distillation on the Pacific coast, Palmer.....	615
Chemistry of the sugar industry, Wohryzek.....	615
Progress made in the manufacture of beet sugar in 1913, von Lippmann.....	615

METEOROLOGY.

	Page.
What the Weather Bureau is doing in agricultural meteorology, Day.....	615
Drought frequency during crop-growing season.....	615
Meteorological reports, Georgeson.....	616
Australian rainfall, Hunt.....	616
The ten-inch line of rainfall, Cherry.....	616
Influence of weather on nitric and nitrous acids in rainfall, Anderson.....	617
Influence of weather on nitric and nitrous acids in rainfall, Anderson.....	617

SOILS—FERTILIZERS.

Thirty-nine experiments in soils, Quear.....	617
Surface formations of northwestern Minnesota, Leverett and Pursell.....	617
Fruit soils in the Sierra foothills, Nelson.....	618
Atmosphere of the soil: Its composition and variation, Russell and Appleyard.....	618
A manometer method of determining the capillary pull of soils, Cannon.....	618
Losses of moisture and plant food by percolation, Fraps.....	619
Effect of moisture content on nitrogen fixing power, Lipman and Sharp.....	619
Effect of organic soil constituents on nitrogen fixation, Reed and Williams.....	620
Nitrogen fixation and nitrification in various soil types, Reed and Williams.....	620
The organic nitrogen of Hawaiian soils, Kelley and Thompson.....	621
Notes on methods for examination of soil protozoa, Martin and Lewin.....	621
Studies on soil protozoa, Cunningham.....	621
Studies on lime requirements of certain soils, Hutchinson and MacLennan.....	622
Probable combination of the chlorin ions in alkali salts, Hare.....	623
The effect of arsenite of soda on the soil, McGeorge.....	623
The influence of zinc vessels in culture experiments, Ghedroiz.....	623
Effect of fertilizers and stimulants on <i>Corchorus capsularis</i> , Albano.....	624
Various forms of dung, Gilchrist.....	624
Green manuring table, Arndt.....	624
German nitrogen monopoly.....	624
Lime nitrogen, Kindler.....	624
Cyanamid in complete fertilizer mixtures, Franke.....	624
Phosphates in Massachusetts agriculture: Selection and use, Brooks.....	624
Phosphoric acid and potash fertilization in the spring, Schneidewind.....	625
Potash salts, 1914, Phalen.....	625
Radium fertilizer in field tests, Hopkins and Sachs.....	625
A municipal fertilizer plant at Los Angeles, California, Heinly.....	625
The international movement of fertilizers.....	626
Importation of fertilizer materials, Ordoñez.....	626

AGRICULTURAL BOTANY.

Measurement of electrical conductivity, Stiles and Jörgensen.....	626
A new theory regarding the feeding power of plants, Truog.....	626
Inorganic iron compounds in the chloroplasts of the green cells, Moore.....	627
Nitrites in plants, Aso and Sekine.....	627
Free nitrogen and higher plants, Molliard.....	627
Studies on anthocyanin bodies, Gertz.....	627
A new method of so-called water culture, II, Hiltner.....	628
Antagonism and balanced solutions, True.....	628
The osmotic pressure of the juices of desert plants, Harris et al.....	628
Relations between osmotic pressure and regulation of stomata, Iljin.....	628
The problems in a comparative study of transpiration in plants, Iljin.....	628
Carbon dioxid concentration and transpiration and development, Kisselew.....	628
The effects of high temperatures on leguminous seeds, Neuberger.....	629
Death of young plants from heat, Schuster.....	629
The action of attenuated acid gases and smoke on plants, Wislicenus.....	629
Forest injury from coal smoke, Baltz.....	629
Physiological characters of plants, Ivanow.....	629
On the nature of mutations, Gates.....	630
Induced variations in chromogenesis, Smirnow.....	630
Influence of concentration of nutrient substrate on micro-organisms, Northrup.....	630
Halophytic and lime-precipitating bacteria, Kellerman and Smith.....	630
Bacteria of the colon type occurring on grains, Rogers et al.....	631
Chondriosomes and their significance, Cavers.....	631

FIELD CROPS.

	Page.
[Report of the] department of agronomy, Knight.....	631
Report of [field crops] work at Fairbanks Station, Neal.....	631
Report of [field crops] work at Rampart Station, Gasser.....	632
[Report of field crops work at Kodiak Station], Snodgrass.....	632
Crop-growing suggestions to dry land farmers, Atkinson.....	632
Crop production in the Great Plains area, Chilcott et al.....	632
Cereal experiments at the Williston substation, Babcock.....	633
The effect of different methods of inoculation, Army and Thatcher.....	633
Results of lucern tests, season 1914-15, Richardson.....	634
Alfalfa, Carver.....	635
Suggestions to alfalfa growers, Atkinson and Wilson.....	635
Studies on bean breeding.—I, Types of yellow eye beans, Pearl and Surface.....	635
Seed values of maize kernels, butts, middles, and tips, Lacy.....	635
Flax for seed and oil.—Harvesting and storing the crop, Bolley.....	636
Flax crop conditions for 1915.....	636
The potato crop in Montana, Whipple.....	636
Potato spraying and dusting in New Jersey, U. S. A., Cameron.....	636
Experiments in covering cane by plow and by spade, Rosenfeld.....	636
Possibilities of the sweet potato in Macon County, Alabama, Carver.....	636
Notes on the germination of tobacco seed, II, Goodspeed.....	636
The chemical composition of the tobacco plant, Pannain.....	637
A study of Colorado wheat, Headden.....	637

HORTICULTURE.

[Horticultural investigations in Alaska], Georgeson.....	637
Biennial report State Horticultural Commission of Utah to November 30, 1914.....	638
The determination of humidity in the greenhouse, Blake.....	638
The origin and history of some of our more common garden vegetables, White.....	638
Morphological and biological researches on radishes, Trouard Riolle.....	638
The origin of the radish.....	639
Tomato culture in Montana, Schermerhorn.....	639
Fungicides, insecticides, and spraying calendar.....	639
Bordeaux mixture, Cook.....	639
An American fruit farm, its selection and management, Thorpe.....	639
Systematic cooperation in Nova Scotia, Adams.....	639
The blooming season of hardy fruits, Hedrick.....	639
Ripening dates and length of season for hardy fruits, Hedrick.....	639
Dwarf apples, Hedrick.....	640
The apple in Brittany, Duplessix.....	640
Chemical and biological notes on cherry orchard soils, Harvey and Hooper.....	640
Blight resistance in pears and pear stocks, Reimer.....	640
Peach growing in Virginia, Starcher.....	641
Inheritance of certain characters of grapes, Hedrick and Anthony.....	641
Spraying for the control of mildew and leafhoppers on grapevines, Foster.....	642
Factors governing successful shipment of red raspberries, Ramsey et al.....	642
Ettersburg strawberries, Clausen.....	642
The citrus grove, its location and cultivation, Rolfs.....	642
The fertilizer requirements of citrus trees, Webber.....	642
Suggestions on coffee planting for Porto Rico, McClelland.....	643
Coffee: Its cultivation and manuring in South India, Anstead.....	643
Notes on the spraying of tea, Andrews and Tunstall.....	643
Bearing dates for grafted shagbark.—A new method for grafting, Morris.....	643
Industrial cultivation of aromatic plants for essences and medicines, Craveri.....	643
Crossing experiments with canna varieties, Honing.....	644
Heredity of color in <i>Phlox drummondii</i> , Gilbert.....	644
The National Rose Society's rose annual for 1915, edited by Darlington.....	644
Italian gardens of the Renaissance, Cartwright.....	64

FORESTRY.

[Forestry report for 1914].....	644
Report on forest administration in Bengal, 1913-14, Muriel.....	644
Report of forest administration in Coorg, 1913-14, Tireman.....	644
The State and forestry in Ireland, Forbes.....	645
The Tintern crown forests, Schlich.....	645

	Page.
Some developments in reforestation on the National Forests, Tillotson.....	645
The quadrat method as applied to investigations in forestry, Sampson.....	645
Harmful effects of grasses and weeds around young trees, Armstrong and Pratt..	645
Some methods in the germination tests of coniferous tree seeds, Boyce.....	645
Variation in the size of ray pits of conifers, Brown.....	645
A new industry in Middle Park: Collection of lodgepole pine cones, Upson....	645
The older forest plantations in Massachusetts.—Conifers, Simmons.....	645
Structure of the wood of Himalayan junipers, Rushton and Paddington.....	645
Relation-ships of the white oaks of eastern North America, Cobb.....	646
Discussion on the eucalypts and their products, Smith.....	646
Culture of <i>Manihot glaziovii</i> at Bokala, Middle Kongo, Janssens.....	646
Treatment of the Para rubber trees of Botanic Gardens, Singapore.....	646
Rattan supply of the Philippines, Arnold.....	646
Wood-using industries of the Prairie Provinces, Lewis and Boyce.....	646

DISEASES OF PLANTS.

The vegetable parasites of cultivated or useful plants, Ferraris.....	646
Fungus diseases, Anderson.....	646
Overwintering of parasitic fungi by means of mycelium, Treboux.....	647
A new North American Endophyllum, Arthur and Fromme.....	647
<i>Rhizostilbella rubra</i> , a by-fruit form of <i>Ascobolus parasiticus</i> , van der Wolk.....	647
Abnormal distribution of fruiting bodies in <i>Ustilago tritici</i> , Riehm.....	647
Mildew of the peach and rose, Woronichin.....	647
Deformation of oat leaves, Zade.....	647
<i>Stagonospora cassavae</i> n. sp., van der Wolk.....	647
Two physiological affections of Sea Island cotton in the West Indies, Nowell..	648
Cruciferous club root and gall weevil injury, Schlumberger.....	648
<i>Rheosporangium aphanidermatus</i> , parasitic on sugar beets and radishes, Edson..	648
Apple spraying experiments in 1914, Morse and Shapovalov.....	648
<i>Plectodiscella piri</i> , representing a new Ascomycete group, Woronichin.....	649
Silver leaf, Schoevers.....	649
Red raspberry injury caused by <i>Sphaerella rubina</i> , Sackett.....	649
Bordeaux mixture as a citrus spray, Fawcett.....	649
Fungi parasitic on the tea plant in northeast India, III, IV, Tunstall.....	650
<i>Ascochyta clematidina</i> , cause of stem rot and leaf spot of clematis, Gloyer.....	650
Dying out of oaks in Westphalia, Baumgarten.....	650
Species of <i>Loranthus</i> on rubber trees, Brooks.....	651
Infection of wood by <i>Coniophora</i> , <i>Trametes</i> , and <i>Polyporus</i> , Wehmer.....	651
The chemical action of the dry rot fungus on the substance of wood, Wehmer..	651
The toxicity to fungi of various oils and salts, Humphrey and Fleming.....	651
Toxicity of various wood preservatives, Humphrey and Fleming.....	651
<i>Wallrothiella arceuthobii</i> , Weir.....	651

ECONOMIC ZOOLOGY—ENTOMOLOGY.

Elementary text-book of economic zoology and entomology, Kellogg and Doane..	652
Studies in the longevity of insects, Baumberger.....	652
Key to the families of North American insects, Bues and Melander.....	652
Injurious and beneficial insects of California, Essig.....	652
The injurious insects of the Government of Moscow, Korolkov.....	652
Fungus diseases and insect pests noticed in 1913, Tupizin.....	652
Deformed apples and the causes, Caesar.....	652
The control of insect enemies of the vine, Bernard.....	652
<i>Hyponomeuta malinellus</i> and <i>Carpocapsa pomonella</i> , Brunner.....	653
The tree crickets of New York: Life history and bionomics, Fulton.....	653
Destruction of <i>Stauronotus maroccanus</i> by <i>Coccobacillus acridiorum</i> , Réguet....	653
Morphological studies on head and mouth parts of Thysanoptera, Peterson.....	653
Experiments in the control of <i>Lecanium cerasi</i> , Ossipov.....	653
New species of Coccidæ collected in Italy, Leonardì.....	653
Possible poisoning of insectivorous birds in war against gipsy moth, Howard..	653
Dispersion of gipsy moth larvae by the wind, Collins.....	653
The millet caterpillar, Hempel.....	654
Control of the army cutworm, Cooley.....	654
New pest of Egyptian cotton, the pink bollworm (<i>Gelechia gossypiella</i>), Gough..	655
An enemy of cultivated carnations, Molinas.....	655

	Page.
Life history of <i>Eucosma haracana</i> , Busck.....	655
Leaf miner of citrus (<i>Phyllocnistis citrella</i>), Rutherford.....	655
Life histories of North American Tineina, Braun.....	655
Descriptions of new Microlepidoptera of forest trees, Busck.....	655
On <i>Mnemonica auricyanea</i> , Busck and Böving.....	655

Effect on appetite of the air of occupied rooms, Winslow and Palmer.	664
The respiratory exchange in fresh-water fish, II, Gardner and Leatham.	664

ANIMAL PRODUCTION.

The stockfeeder's companion, Porter.	664
The international movement of feeding stuffs.	664
Result of official chemists' analyses of feed stuffs.	665
Feeding stuffs, Voelcker.	865
Amino acid content of commercial feeding stuffs, Nollau.	665
The distribution of cyanogen in grasses, Alsberg and Black.	665
Bitter and sweet cassava, hydrocyanic acid contents, Collens.	665
The composition and value of lupine seeds, Muenk.	665
Influence of the mineral content of the ration, McCollum and Davis.	666
[Animal husbandry work in Alaska], Georgeson et al.	666
Chemistry of coat color in animals and of whiteness, Onslow.	667
Case of Hunter's freemartin with reversion to wild park cattle type, Hart.	668
German breeds of live stock.	668
The value of German breeding cattle in German Southwest Africa, Neumann.	668
Lincolnshire Red Shorthorns, Collins.	668
Profits in southern cattle feeding, Curtis.	668
Data on sex determination in cattle, Pearl and Parshley.	669
Study of the form and weight of young cattle, Indermühle.	669
The rearing of calves on substitutes for milk fat and milk, Wale.	669
Blackface sheep, M'Millan.	669
Border Leicester sheep, Smith.	669
"Blanket" system of handling sheep on the Madison National Forest, Fleming.	669
Producing more and better sheep by improvements in handling, Jardine.	670
The "bedding out" system of handling sheep, Wyoming, Douglass.	670
Handling sheep on timber and brush ranges of Idaho, Martineau.	670
The properties of wool, Davis.	670
Dried chicory roots as horse feed, Donegan.	670
Alfalfa hay for hogs, Foster and Simpson.	670
The use of the paunch contents of freshly slaughtered cattle as a pig feed.	672
The Large White Yorkshire pig, Heaton.	672
Poultry, Rolf and Payne.	672
Telling the sex of day-old chicks, Fry.	672
Third annual international egg laying contest, Kirkpatrick and Card.	672
Report on the fourth egg-laying competition at Burnley, 1914-15, Hart.	673
Parafield egg-laying competition, Laurie.	673
Control of the marketing of eggs, Behre and Frerichs.	673

DAIRY FARMING—DAIRYING.

Progress in milk chemistry and dairying during 1913, Grimmer.	673
The practicability of starch values in dairy cattle feeding, Sjollema.	673
Feeding experiments with dairy cows, Flückiger and Indermühle.	674
The effect of palm-oil cakes upon milk production in cows, Hansen.	674
Influence of sugar beet feeding on composition of milk fats, Boes and Weyland.	674
Grass palatability tests, Breakwell.	674
Reaction and calcium content of milk as factors in coagulation, Milroy.	674
Relation of <i>Streptococcus lacticus</i> to acid in milk and cream, Heinemann.	675
The alkali-forming bacteria found in milk, Ayers and Rupp.	675
The preservation of milk by freezing, Fascetti.	675
The refrigeration of a city's milk supply, Bates.	675
The resistance of lactic acid bacteria to pasteurization, Peiser.	675
Silicic acid in milk from sterilization in glass bottles, Pfyl.	675
[Waste in milk delivery].	675
Using the Babcock test, Fuller.	676

VETERINARY MEDICINE.

Department of veterinary science and bacteriology, Mack.	676
The detection of anthrax bacilli in the bone marrow, Grabert.	676
Foot-and-mouth disease in Denmark, Dunne.	676
Studies on the biochemistry and chemotherapy of tuberculosis, X, Hirsch.	677

	Page.
Studies on the biochemistry and chemotherapy of tuberculosis, XI, Corper....	677
Tubercle bacilli in nontuberculous respiratory passages, Titze and Lindner....	678
Hog tuberculosis and its significance for meat hygiene, Nieberle.....	678

EXPERIMENT STATION RECORD.

VOL. XXXIII.

NOVEMBER, 1915.

No. 7.

The extent to which the element of chance figures in agricultural experimentation and investigation is a large one. It is at once the inspiration and the distraction of the seeker after new truth. It accounts for many efforts which are in part futile for the time being, and for frequent negative or unenlightening results, as well as for occasional findings of great significance.

This recognition of the uncertainties in the situation is not opposed to the idea that agricultural investigation is of an exact nature and is based on the best available light of the time, but it expresses the groping nature of the effort, the inadequacies of methods, and the inability to control conditions which may be adverse to a conclusive result. While these difficulties are common to other branches of science, they are perhaps especially conspicuous in agricultural experimentation and investigation, owing to the very complex nature of the problems and the conditions under which they are studied. The acknowledgment of them is not a sign of weakness or of doubt, but rather of a clearer insight which has come with the extended experience of our stations in that field.

The very nature of research and experimentation implies the element of doubt, the uncertainty as to the ultimate outcome. If there were no question there would be no need for experiment. While not a random effort, it involves novel and often abnormal factors and conditions which can not be fully depended upon and are in part undetermined.

No one can predict the result of an experimental inquiry, or prophesy as to its success. It is an attempt to find out something that is not known. While it is not a leap in the dark it is an excursion into the unknown, and the paths are not clearly charted. The method of approach is suggested by analogies, but it requires some adaptation to each particular case and it may prove inadequate or present stumbling blocks. In that case it calls for ingenuity and a careful consideration of all known facts and factors. In many instances the successful attack of a class of problems calls for an original conception as to the nature of the project and the way in which it might be successfully attacked. In any event it requires close application. There is a difference between working upon a question

and working at it. One has an objective, constructive aim, and a method which embodies all that the best knowledge and experience and ingenuity can suggest; the other works around the edges of the question, searching for a lead and waiting for something to turn up.

While some of this uncertainty is manifestly unavoidable, and arises in a measure out of the general deficiencies of knowledge, it is increased by haste, deficient preparation, insufficient attention to details, and other matters which have a pronounced effect. It results from insufficient planning, from undertaking more than can be done thoroughly, and from failure to study the data as they need to be studied. In some cases it is a result of following the practical phase of the problem too closely and exclusively.

A recent writer in commenting upon the experimental inquiry in a given line said: "Unfortunately the trail of the 'practical man' was followed somewhat too closely in the investigations which were made before the end of last century, with the result that many field experiments have expressed the natural result of many conflicting factors, and have given but little indication as to the components." There is much truth in this statement, and it probably applies to considerable of the experimental work of the present. It results from the attempt to meet the expectations of the public by giving direct answers to practical questions as speedily as possible. But in this attempt it fails to realize that "the principle underlying an agricultural problem must first be studied before the problem itself can be solved." This is why at the outset close analysis of a practical agricultural question is essential, and the devising of a plan which will give an intelligent and satisfying answer as far as it goes.

The object of an experiment or an investigation is to secure definite information—to establish a fact, to test a theory, or to determine the application of certain results. The aim and the plan, therefore, should be to give as distinct and conclusive an answer as is possible. It may not be complete but as far as it goes it ought to be authentic and reliable. It should not be forgotten that the genuineness of discovery is of first importance, and furthermore, that, as a great lawgiver has said, to know the law we must understand the law. Both are opposed to haste and superficiality.

In some of our undertakings the element of chance is at times unnecessarily large. It does not fully take account of the experience and the teachings of experimental work. Occasionally the prophecy might almost be made at the outset that neither final nor probably illuminating results would follow. The difficulty may be inherent in the subject, because of lack of insufficient information leading up to it; investigation may not have progressed far enough to enable constructive and conclusive work. This accounted for much of the

unproductive work on the biology of the soil in years past, and to some degree this general lack of information apparently still blocks progress.

Science rarely progresses by leaps and bounds, but piece by piece. Chance discoveries of great moment are seldom made at random. Knowledge advances by a process of accumulation and through a deeper insight which suggests more effective methods of attack.

In a certain class of station work there is considerable collection and accumulation of data merely on the chance or in the hope that it may develop something of interest, or shed light on the nature of some class of phenomena. It is rarely a promising method where a definite ultimate object is in view, and unless something definite is being looked for the point of importance may escape notice. Where the first essential step is to get a substantial basis of data or a record of natural phenomena the case is, of course, quite different.

Some workers are more willing than others to take chances. They unnecessarily admit the element of doubt, partly because they may not be fully conscious of it, and partly because they are impatient of slow methods. Inexperience and overconfidence in the capabilities of experiment are often responsible for this. Someone has said that a spirit of experiment and a contempt for the past "has made us credulous of quick improvement, hopeful of discovering panaceas, confident of success in every new thing."

There is a kind of experiment which deals with matters superficially—which seeks only the answer without regard to how it is derived or how it may be limited—in fact, without determining just what it means. It does not aim at the real underlying question and go to the bottom of it, but it conducts hasty tests and trials which are incapable of giving more than a partial, superficial answer; it mistakes a comparative result for an absolute answer, and ventures a deduction or generalization which later is found unwarranted.

Happily this type of work has quite largely passed. It has been found inadequate and dangerous. It has no place in an enterprise which seeks illuminating and dependable facts. But there is still a considerable body of work which is superficial and incomplete in that it does not go to the kernel of the matter and contents itself with results which are at best temporary and tentative, without planning studies which will make them more logical and stable. Much of this work gives only comparative results, tentative and empirical at best, but the chance is taken of generalizing from it broadly. And there is some disposition to perpetuate work of this kind instead of engaging in a type which is more thorough and conclusive. It is in part a matter of training and of insight, and to some extent it is because such grade of work meets with quick re-

sponse and appreciation. For this reason it is countenanced, although its limitations are not unknown, and the higher standards are not made a requirement.

We realize, for example, that many of the field experiments so extensively conducted are less accurate and dependable than such studies ought to be, because of their inherent crudeness and because of factors which are not checked or controlled. A considerable experimental error is recognized, dependent upon a variety of factors, and the limitations of such work have been widely demonstrated. Furthermore, in outdoor experiments the chance factors of the season have a very large effect. But field experiments unsupported by more refined studies continue to form a large feature of the work in agronomy. Considerable of our breeding work with plants rests on chance. It seeks the chance result, a product and not an idea, and contrives to increase the probability of its appearing. This is its primary object rather than an attempt to find out why, how, and under what conditions these exceptional things occur. Instead of studying correlations with a view to a greater elimination of chance in breeding, emphasis is placed first and foremost on the attempt to get something better, and there the undertaking often rests.

Feeding experiments made from the commercial or economic viewpoint are subject to market fluctuations, and hence embody an additional chance element. And it frequently happens in such experiments that untoward conditions or accidents occur which make a clear interpretation of results impracticable.

Haste is responsible for another element of uncertainty in various kinds of experiment, which in the end is wasteful of time and energy. It is supposed to be a common attribute of Americans. The Englishman has accused us of acceleration as a national characteristic—of haste in all things, instead of inquiring whither. Scientific progress in agriculture has never been as rapid at any period as at the present, but this apparently has served to increase expectation and resulted in a speeding up. Rapid as the progress is, there are those who seem to feel that the great questions which have been before the world for centuries should now be answered without much delay.

Referring to the necessity for the exercise of patience in regard to research, Dr. D. P. Penhallow, in an address delivered several years ago, pointed out that nature's processes, although exceedingly certain of fulfillment, are nevertheless exceedingly slow. "If it has taken five hundred million years to shape this earth and render it a fit habitation for man, man himself must not be impatient if he is required to spend a few years of arduous toil that he may unlock some of the doors which so carefully guard nature's secrets.

Sixty-three years sped on their way from the time when Boussingault first endeavored to ascertain the source of nitrogen in plants, until a satisfactory explanation was reached through our knowledge of the action of root tubercles; and for more than sixty years Lawes and Gilbert sought the solution of plant nutrition without gaining the end in view.

“The laws of nature are not kept on draught, as it were, to be drawn in large or small quantity, according to the demand. To present a problem to an investigator and expect an immediate solution, or an immediate practical application, is to be prodigal of a costly equipment, to sacrifice unnecessarily the best and most carefully trained intellectual strength, and to bring discouragement and invite failure.

“It is, no doubt, true that when a commonwealth has invested a large amount of capital in specially trained men and expensive apparatus, it is reasonable to ask for results, and with this no fault can be found. The danger lies in the fact that sufficient opportunity is not allowed for the careful working out of a problem in all its scientific aspects. Under conditions of haste and undue pressure, the results, if worth anything, are very likely to be incomplete and unsatisfactory, and in too many cases they must be subject to costly revision.”

There is abundant confirmation of the truthfulness of these views in our own experiment station work. It is no disparagement but a note of caution. The necessity for less haste and for patience with the more thorough and leisurely methods ought to be understood. Most of the simpler things have been done. From now on the progress may be more slow, but it ought to be more sure.

The element of chance in a certain type of experiments is further increased and multiplied by a large amount of repetition, because of inadequacy of the methods or the means of attack. The error involved is not eliminated, and hence the chance of misinterpretation is accumulated and increased. Mere imitation will mark but little advance, for it lacks the critical attitude and the searching spirit essential to improvement and progress. What is most needed is new thought and ideas, and new insight, rather than more experiments which mark no special progress. These are now essential as a means of successfully attacking problems which, although much worked upon, have not yielded to the experimental method, or at least only in part. In some lines the attempt is still being made to work out through relatively crude experiments, unaided by more refined methods, problems which will require quite different treatment. One value of earlier experiments lies in disclosing the weak-

nesses and limitations of methods, which continued repetition and study from the same point of view serve mainly to confirm.

Not all topics which it is desirable to know about are profitable ones for study at the present time. The element of uncertainty is too great; they wait on further advancement in the field of general science. How futile it now seems to have experimented on the control of a plant disease until we knew something of the history, habits, and manifestations of the organisms causing it. It was like prescribing remedies in human medicine before the real nature of the disease was known. In much the same way some of our work at present attempts to attack complex problems too directly. It seems unpromising, for example, to attempt a direct study of the effect of a course of soil treatment on the fertility of the soil until we can measure more accurately the different elements that go to constitute fertility and correlate them so as to trace a direct relation between the treatment and the complicated nature of the manifestation. It is obvious that in agricultural investigation, as in all kinds of research, the scientist should not compare effects without studying causes or enlarge upon results without examining their origin and source.

Our knowledge and our ability to conduct profitable researches go forward step by step, and agricultural research is so dependent on the advance of general science that it can rarely do more than keep pace with it. We should not, therefore, take unnecessary and unreasonable risk in selecting topics for study. This does not mean that the easy things should be selected, but those whose profitable study is practicable—the things it is feasible to do or which give promise of being solved. Such a selection implies close critical study of the station's program of work.

The element of chance may be increased by the way in which the station program is made up. It seems at times to be itself something of a matter of chance. It lacks evidence of system or a general plan. It skips from one thing to another without continuity or visible connecting link. The work in one department does not supplement that in another, much as the need for it may be. The program as a whole is to some extent a chance combination, growing out of contingency and of what the members of the staff, acting and thinking independently, decide they would like to take up. In other words, there is a suggestion of lack of coordination.

The station program ought not to be a heterogeneous admixture of independent, unrelated lines of work, without system or plan, but it ought to have regard to the efficiency of the station as a whole and to both the needs of agriculture in the State and the needs of agricultural science as a means of advancement.

It will have occurred to the reader that perhaps the largest element of chance lies in the human equipment. The ability of a station to enter upon a given piece of new work hangs on the chance of getting some one competent to take charge of it, and his qualification can not always be determined in advance. Even when such a worker is secured and is making encouraging progress, a successful issue is contingent on the ability to retain him. This is being continually brought home to the stations. To provide the necessary men of proper equipment, special efforts are being put forth, and to insure the continuity of investigations, attempts are being made to link the leaders more closely to their special problems.

In the past what the station was doing depended to no small extent on what the men could manage to fit into their other duties, and what they were able to accomplish depended on their ability to adjust their studies to the opportunity which the year brought forth. It has not been unusual for men to explain that they did not take up certain exacting lines of study because they knew their other duties would probably not permit them to follow these studies continuously or to devote the necessary time to them.

With the larger measure of relief of station investigators from other duties and from interruption, these elements of uncertainty are constantly growing smaller. The station's program at the present time is, to a far less extent than formerly, contingent on circumstances and other demands on its working staff. But the case of the supervising and coordinating head of the station, on whom general direction depends and to whom the men should look for stimulation and encouragement, is less favorable. He is often attempting to do too much and too great a variety of things, which leaves insufficient time for consideration of the station's work and management. The effect of this is to increase the element of chance, because it is inadequately guarded against.

A primary object of the experiment station is to remove the element of chance in farming—to make the art better understood and more certain in its results. The greater confidence of the public in experimenting and the extent to which the stations' teachings are now being incorporated into practice make it doubly necessary for the experimenter to be conscious of the elements of error, to make haste slowly, and to develop his studies along an orderly constructive program.

It behooves us to make experiment and investigation in agriculture as secure and adequate as possible, both in method and result—to eliminate or reduce to the lowest practicable terms the chance of failure or ineffective effort. The means for this are a part of the

general problem. The spirit of investigation involves the discovery and overcoming of obstacles. It is in this way, instead of by going around them or passing them on, that advancement is made. Some of the present uncertainty is avoidable or capable of being brought more largely under control than it is in many cases, and supplemented by more exact studies. There is opportunity for searching inquiry as to the adequacy of plans and methods involved in new undertakings and in lines which have been under way for a period; and there is good opportunity for a larger measure of sympathetic, constructive criticism. When everything is done that science and experience suggest, there is a sufficient chance element standing in the way of progress, and without progress our experiment stations would soon cease to be leaders in this great educational effort.

RECENT WORK IN AGRICULTURAL SCIENCE.

AGRICULTURAL CHEMISTRY—AGROTECHNY.

The acids and colloids of humus, G. FISCHER (*Kühn Arch.*, 4 (1914), pp. 1-136, figs. 4).—In this work the colloids of humus were isolated by either the cold or hot water extraction methods, with filtration through hardened quantitative filters, asbestos or Pukall's filters, and concentration in vacuum at 30° C. or at ordinary pressure. The concentrates were purified by either parchment paper or fish bladder, by ultrafiltration, precipitation with alcohol, acetone, etc.

The method of preparing the humus did not seem to have any effect upon the reactions, but it has not been established whether the hot-water treatment can be used in other instances. On account of the higher concentrations of the Pukall filtrates of the hot-water extracts, the observations could be more easily made on these solutions.

The colloids of the cold-water treatment of composts in some cases showed other reactions. Humus colloids passed through 7.5 per cent ultrafilters. The colloids remaining in the ultrafilter with one exception were irreversible, but the ultrafiltrates still contained typical colloids, as was proved by flocculation, cataphoresis, and ultramicroscopy.

The hydrogen ion concentration of the various soils examined was determined by direct measurement of the electromotive power on the nonpurified and dialyzed solutions of humus. The crystalloid cations were removed from the colloid salt by dialysis. No illusion of an acid reaction with an indicator like litmus which depends on the absorption of the coloring matter cations could be noted.

Migrating capacity and velocity were determined with and without the addition of acid or alkali in unpurified and dialyzed colloids. The electric charge was negative, and the migrating velocity was least in acid media. Black soils were not examined. The migrating velocity of the dispersive phase of the same solution was ununiform, and the electric potential of the colloid particles was not constant.

By covering with water in the modified Coehn apparatus, partial coagulation occurred. This was irreversible in unpurified colloids, with one exception, but reversible after purification.

Protective properties were not possessed by humus colloids against colloidal gold and clay. There was protection against iron oxid, but it was not identical with that of reversible colloids. Reduction of colloidal iron oxid by humus colloids was not observed. The precipitation optimums of humus sols and sesquioxids were, in some cases, established. The humus colloids were not sensitive toward electrolytes. Reduction of gold chlorid hydrochlorid in the presence of humus was not noted. The dry state of humus sols in soils in most cases was irreversible.

A chemical analysis of the inner organic constituents of the soil in most cases gave no insight into the composition of colloids, but only emphasized the organic nature of humus colloids. Microscopically examined, the solutions of colloids were found homogeneous. Greenish-yellow and yellowish-red particles were visible with the ultramicroscope. Humus colloids were not found to be typical,

reversible hydrosols, but appear to be related to certain organic coloring matters.

A new reaction for clay, F. RATHGEN (*Tonindus. Ztg.*, 38 (1914), No. 3, pp. 30, 31, fig. 1; *abs. in Chem. Ztg.*, 38 (1914), No. 14, *Repert.*, p. 57).—This is a microchemical reaction which will detect aluminium and aluminum compounds in all substances, even though they be present in traces. e. g., in green or brown bottle glass. To 1 gm. of the powdered substance under examination in a platinum dish is added a little ammonium fluorid and 4 to 5 drops of concentrated sulphuric acid, and heated gently to dryness. As a result corundum is formed, which may be recognized under the microscope as six-sided colorless plates. When iron is present there are formed yellowish to brownish six-cornered crystals surrounded by a border of colorless corundum. Light-green (very small) and bluish six-cornered crystals point to the presence of cobaltic and chromium oxid, respectively.

A review and discussion of some of the methods for the determination of alkali in soils, R. F. HARE (*New Mexico Sta. Bul.* 95 (1915), pp. 7-16).—This is the report of the associate referee on alkali soils to the Association of Official Agricultural Chemists at Washington, D. C., November, 1914 (E. S. R., 32, p. 296). It reviews and discusses methods used by the Bureau of Soils of this Department and by several of the state experiment stations for the determination of alkali in soils.

Comparative investigations of Thomas slag powders according to the Lorenz, Naumann, and Popp methods, W. HOLLE (*Chem. Ztg.* 38 (1914), Nos. 112-113, p. 1083).—In these investigations it was found that the Lorenz method gave lower results than the Popp and Naumann methods, the two last-named methods being considered about on a par. The best results can be obtained by the Lorenz method, but the procedure is cumbersome. See also the work of Haussding (E. S. R., 31, p. 410).

Methods of bacterial analyses of air, G. L. A. RUEHLE (*U. S. Dept. Agr., Jour. Agr. Research*, 4 (1915), No. 4, pp. 343-368, figs. 3).—This study was undertaken at the New York State Experiment Station in connection with the relation of the bacterial content of stable air to the amount of bacterial contamination of milk. It is devoted especially to a determination of the filtering efficiency of two aeroscopes and a modification of one of them.

"It seems reasonable to conclude that the nature of the filters tested had little influence on the results secured in duplicate analyses, that is, those obtained where a sand and a liquid filter were used side by side agreed just as well as those where either two sand filters or two liquid filters were used side by side. It was found that the particular form of sand-filter aeroscope recommended by the committee on standard methods of bacterial air analysis appointed by the American Public Health Association varied in its filtering efficiency from 50 to 100 per cent, with the average efficiency for two series of tests of 90 and 91.6 per cent. It is believed that the chief cause of error with this form of aeroscope arises from the fact that it is so constructed that it must be sterilized with steam, which causes caking of the sand-filtering layer."

The modification of the standard aeroscope differs from the standard instrument in that the lower rubber stopper and the bolting cloth supports are eliminated and the small tube is fused into the larger one. The layer of sand is supported by a layer of cotton, resting on the shoulder at the junction of the large and small tubes. The upper stopper is replaced by a cork, which permits sterilization of the aeroscope by dry heat instead of steam.

"The modified standard aeroscope was found to retain nearly 100 per cent of the bacteria, with little chance of error. It was also found to be cheaper,

less breakable, easier to operate, and more adaptable to field work than either the standard sand aeroscope or the aeroscope recommended by Rettger. The latter can be made to yield excellent results, provided sufficient care is exercised in handling it. Its use, however, is attended with a number of difficulties, among which may be mentioned its tendency to leakage about the rubber stoppers after being sterilized, the foaming of the liquid during operation, and the tenacity with which the bacteria cling to the inner surface of the moist inlet tube.

"The method of determining bacterial precipitation from air by means of exposed Petri plates has been found to be entirely unreliable, as it gives a measure of the number of bacteria-laden dust particles and not a measure of the number of bacteria present. The number of bacteria precipitating upon a given area has been determined by analyzing measured quantities of sterile water which had been exposed to the air for a given length of time in sterile pails. The numbers obtained in this way were from 2 to 32 times higher than those obtained with the plate-exposure method."

A bibliography of cited literature is appended.

The differentiation of various kinds of yeast with the aid of specific agglutinins, LICHTENSTEIN-ROSENBLAT (*Wchnschr. Brau.*, 31 (1914), pp. 293-295; *abs. in Ztschr. Angew. Chem.*, 27 (1914), No. 85, *Referatenteil*, p. 592).—Rabbits receiving intravenous injections of pure cultures of yeast yielded blood sera which could be used in the agglutination test for differentiating not only the various *Saccharomyces* (top and bottom fermentation yeasts) but also for differentiating torulas from *Saccharomyces*.

Picric acid as a titrametric standard, O. PFEIFFER (*Ztschr. Angew. Chem.*, 27 (1914), No. 50, *Aufsatzteil*, p. 383).—Picric acid is advocated as a substance for iodometry and acidimetry. For standardizing acid solutions, however, the author prefers measuring the strength of the original solution with alkali and dimethylamidazobenzol.

The titrametric estimation of free sulphurous acid, E. KEDESZY (*Chem. Ztg.*, 38 (1914), No. 57, pp. 601, 602; *abs. in Ztschr. Angew. Chem.*, 27 (1914), No. 91, *Referatenteil*, p. 625).—The method in which sulphuric acid is titrated with methyl orange until the acid sulphite stage is reached and then with phenolphthalein until the neutral salt is obtained is deemed inexact, since the change in color with phenolphthalein occurs before the formation of the neutral salt is complete. The transition from one stage to the other may be made sharper if one oxidizes the acid salt to the neutral salt with hydrogen peroxid.

A new simple method for determining free sulphurous acid when thio-sulphate or sulphuric acid is present, A. SANDER (*Ztschr. Angew. Chem.*, 27 (1914), No. 26, *Aufsatzteil*, pp. 194, 195).—In this method, which is a modification of Feld's, standardized iodine solution is run in excess into the mixture of sulphurous acid and thiosulphate, and the excess of iodine is determined with standardized thiosulphate solution. The colorless solution is then treated with an iodide-iodate mixture and the liberated iodine is titrated with thiosulphate as before. The method can be used for estimating bisulphates, and also sulphuric and sulphurous acid in admixture.

The chief cause of the loss of sulphuric anhydride and of chlorine by incinerating substances containing these constituents, J. O'SULLIVAN (*Analyst*, 39 (1914), No. 463, pp. 425-428).—The conclusions arrived at are as follows:

Although chlorides are decomposed and chlorine is lost on incinerating organic substances containing chlorides, the sulphates of calcium, potassium, and sodium are not appreciably reduced. Magnesium sulphate undergoes decomposition on ignition unless a carbonate is present. In the absence of a carbonate the ash

of substances containing magnesium sulphate will, when ignited, consist of magnesium oxid. The quantity of magnesium sulphate in a substance containing chlorids may be sufficient to cause the total loss of the chlorine on incineration.

Volumetric determination of copper. G. ZUCCARI (*Ann. Chim. Appl. [Rome]*, 2 (1914), Nos. 9-10, pp. 287-290).—The solution of the salt is titrated with a solution of a sodium nitroprussid which contains 46.866 gm. per liter until a filter paper moistened with ammonium sulphid becomes colored. One cc. of the sodium nitroprussid solution=0.01 gm. of copper. Free acids or salts of ferric iron, zinc (save in high concentration), tin, aluminum, lead, manganese, and certain other metals do not affect the results, and the method can be applied directly to solutions of copper which do not contain nickel or cadmium.

Detection of vegetable fats in animal fats, M. KLOSTERMANN (*Ztschr. Untersuch. Nahr. u. Genussmtl.*, 26 (1913), No. 9, pp. 433-437; *abs. in Jour. Soc. Chem. Indus.*, 32 (1913), No. 23, p. 1118).—The Marcusson and Schilling method was not found always applicable, since digitonin precipitates only free cholesterol and phytosterol and not their esters.

“Saponification is essential, and the following method is recommended: One hundred gm. of the fat is saponified with alcoholic potassium hydroxid, the soap solution diluted with water, and the fatty acids liberated by hydrochloric acid and extracted with 250 cc. of ether. The ethereal solution is washed with water and shaken with 250 cc. of petroleum spirit and about 25 gm. of sodium chlorid, which is subsequently separated by filtration through cotton wool. The filtrate is heated and treated with a solution of 1 gm. of digitonin in 20 cc. of 90 per cent alcohol, and the crystalline precipitate separated after 15 minutes and washed with ether until free from fat. It is then dried with filter paper and acetylated with 20 to 30 cc. of acetic anhydrid. The excess of acetic anhydrid is evaporated, the residue dissolved in 50 cc. of absolute alcohol, and the solution treated drop by drop with water until crystals begin to separate. More water, up to 25 cc. in all, is then added and the crystals filtered on cotton wool, washed with 70 per cent alcohol, and dissolved in ether. The solution is evaporated to dryness and the acetates are recrystallized from absolute alcohol and examined in the usual way.”

The separation of sterins from fats with digitonin, P. BERG and J. ANGERHAUSEN (*Chem. Ztg.*, 38 (1914), No. 93, pp. 978, 979; *abs. in Ztschr. Angew. Chem.*, 27 (1914), No. 91, *Referatenteil*, p. 644).—The value of the Windaus method for separating sterins with digitonin was studied. It was deemed especially desirable to know whether the method could be employed for food-control work, and, furthermore, whether the procedure could furnish new ways for investigating the unsaponifiable constituents of fats.

A modification of the Marcusson and Schilling, Klostermann, and Fritzsche methods (which utilize the Windaus principle) was finally decided upon. The solvent employed was chloroform saturated with digitonin at 60 to 70° C. Twice as much acetic acid anhydrid was employed for acetylation as is recommended by Marcusson and Schilling. For quantitative purposes the Klostermann procedure for separating the acetates is recommended. The sterin-free portion of animal fats does not seem to possess optical activity, but in plant fats and hardened animal fats optical activity of the sterin-free part is often observed. In hardened fats the optical activities are dextrorotary. It is thought that this optical property might eventually be employed for detecting hydrogenated fats.

Methods for the quantitative estimation of mannit, J. SMIT (*Ztschr. Analyt. Chem.*, 53 (1914), No. 8, pp. 473-490; *abs. in Ztschr. Angew. Chem.*, 27

(1914), No. 91, *Referatenteil*, p. 625).—The methods worked out can be divided into three groups: (1) A modification of the Gayon and Dubourg method; (2) separation of mannit compounds of definite composition, when appropriate compounds can be obtained with ketones and aldehydes; and (3) indirect methods which do not involve the separation of mannit.

Determination of the amino acid and polypeptid nitrogen in barley, malt, and beer by the formaldehyde titration method, L. ADLER (*Ztschr. Gesam. Brauw.*, 37 (1914), Nos. 9, pp. 105–108, fig. 1; 10, pp. 117–121; 11, pp. 129–133).—The method described is based on principles similar to those set down by Sørensen et al. (E. S. R., 19, p. 808; 23, p. 217). Phenolphthalein was used as an indicator. See also a note by Schjerning (E. S. R., 32, p. 23).

The presence of citric acid in natural wines, BLAREZ, DENIGÈS, and GAYON (*Ann. Falsif.*, 7 (1914), No. 63, pp. 9–11).—Certain countries do not admit wines which contain citric acid, and this study was made for the purpose of determining whether French wines, especially Sauternes, contain this acid naturally. The method used in the investigation was Denigès.

In 25 wines made in the years 1893, 1903, 1906, 1907, 1908, and 1912 the percentage varied from 0.01 to 0.045. Wines taken from Montbazillac, Anjou, and on the Rhine (1904 to 1911, 13 samples) contained from 0.005 to 0.03 per cent. The juices of 16 samples of red and white grapes were found to contain, before fermentation, from 0.012 to 0.05 per cent and after fermentation, from 0.008 to 0.05 per cent.

Analysis of milk, G. MEILLÈRE (*Jour. Pharm. et Chim.*, 7, ser., 9 (1914), Nos. 10, pp. 489–493; 11, pp. 559–563, fig. 1).—After discussing in a general way the physical methods for density, freezing point, and electrical conductivity, the methods for making quantitative determinations of the components of milk, especially fat, are considered. A modification of Armand Adam's method, which allows the determination of fat, dry matter, lactose, and casein, but not the salts, in the same sample, is proposed. This requires two hours at the longest for making a chemical examination of milk without special apparatus. It separates the milk by means of a mixture consisting of 1,000 cc. of 75 per cent alcohol and 1,100 cc. of ether into a layer of fat and a layer of nonfatty substances. Ammonia is added in sufficient quantity to insure a good separation of liquids. The ethereal layer is drawn off and evaporated on the water bath.

The specific weight of milk serum in the detection of water adulteration, HERRAMHOF (*Molk. Ztg. [Hildesheim]*, 28 (1914), No. 7, pp. 115–118).—It was found that the specific weight of milk serum from different cows shows less variation than does that of the entire milk, that it is correspondingly lowered as the water content increases, and that it remains unchanged after three days' coagulation. It is stated that clouded milk serum may be made clear by filtering through bone charcoal.

Lime-sulphur sprays, their composition and analysis, A. A. RAMSAY (*Jour. Agr. Sci. [England]*, 6 (1914), No. 4, pp. 476–483).—In a previous paper (E. S. R., 31, p. 541) it was stated that the monosulphid sulphur present in lime-sulphur sprays appears to be essentially calcium hydroxyhydrosulphid (CaHSOH) with very minute quantities as calcium hydrosulphid (CaHS_2). "The solution of lime sulphur then appears to consist of calcium hydroxyhydrosulphid, calcium thiosulphate, calcium sulphate with sulphur held in solution." This is now amended by adding calcium disulphid.

The method of analysis is now as follows: Dilute 50 cc. of the concentrated lime sulphur to 500 cc. with water. (1) Titrate 25 cc. of the diluted mixture with decinormal iodine solution till the yellow color is discharged. The number of cubic centimeters used multiplied by 0.0016=sulphur by 0.0028=lime.

(2) Continue the addition of decinormal iodine solution till a tinge of yellow color obtains. The number of cubic centimeters decinormal iodine added multiplied by 0.0064=sulphur as thiosulphate and by 0.0056=lime (CaO) in combination as thiosulphate. Starch paste or paper may be used in (1) and (2) but the addition of starch renders filtration of (2) difficult to proceed to (3).

"(3) The fluid used in (2) is filtered through double filter paper and washed with cold water. To the filtrate barium chlorid and a few drops dilute hydrochloric acid are added, and the whole allowed to stand all night in the cold. Barium sulphate is filtered off, washed, dried, ignited, and weighed. The weight obtained multiplied by 0.1373=sulphur present as sulphate and sulphite. The sulphur multiplied by 1.75=lime equivalent to sulphur as sulphate and sulphite.

"(4) Ten cc. of the diluted mixture is diluted with about 25 cc. water and is shaken up in a separating funnel with 10 cc. carbon bisulphid, and allowed to separate. The carbon bisulphid is drawn off into a tared Erlenmeyer flask. The diluted mixture in the funnel is again extracted with 10 cc. carbon bisulphid and finally with two lots of 5 cc. each—the carbon bisulphid after extraction being added to that already in the tared flask. The carbon bisulphid is now removed by placing the flask in warm water, and the flask and contents dried to constant weight at a low temperature (not exceeding 70° C.). The sulphur obtained is free sulphur.

"(5) To 10 cc. of the diluted mixture, about 6 or 8 gm. sodium peroxid is added to oxidize the mixture, which is allowed to stand a few minutes. Fifty to 75 cc. water is added, and then hydrochloric acid, cautiously, till the solution clears up. Add a few drops of potassium iodid solution (15 gm. KI in 100 cc. water) to reduce the higher oxids (of chlorine)—boil off the excess of iodine—dilute with water to about 200 cc. and precipitate sulphur as BaSO₄. Filter, dry, ignite, weigh, and calculate to sulphur by multiplying weight of precipitate by 0.1373. This gives total sulphur.

"(6) To another 10 cc. aliquot of the diluted mixture, decinormal iodine solution is added as previously described till sulphids and thiosulphates are decomposed as at (1) and (2). Filter sulphur off through double-filter paper. Make filtrate ammoniacal, and determine the lime by precipitation with ammonium oxalate. This gives total lime. Calculations: (a) Sulphur obtained at (5)—[sulphur (4)+sulphur (3)+sulphur (2)]=sulphur as hydroxyhydrosulphid and disulphid= a . (b) Lime obtained at (6)—(lime calculated at (3)+lime calculated at (2))=lime as hydroxyhydrosulphid and disulphid= b . Let x =lime in combination as hydroxyhydrosulphid then $b-x$ =lime in combination as disulphid. Further, $x \times 0.5714$ will be the sulphur in combination with x lime as hydroxyhydrosulphid and $b-x \times 1.1428$ the sulphur with $b-x$ lime as disulphid. Then

$$x \times 0.5714 + (b-x) \times 1.1428 = a,$$

$$x = \frac{(b \times 1.1428) - a}{0.5714}$$

from which $b-x$ is found."

The technical method for manufacturing dicyanamid from lime nitrogen from the standpoint of chemical kinetics, G. GRUBE and P. NITSCHÉ (*Ztschr. Angew. Chem.*, 27 (1914), No. 50, Aufsatzteil, pp. 368-378, figs. 4).—A discussion of the methods and the results of some experimental work in this direction.

Formation of furfural from wood during the steaming process, E. HEUSER (*Ztschr. Angew. Chem.*, 27 (1914), No. 100, Aufsatzteil, pp. 654, 655).—All furfural obtained from straw or wood which is undergoing a process of steaming at 4 atmospheres originates from the pentosans which the substance contains.

No furfural results when wood or straw is steamed or boiled at atmospheric pressure. When xylose in water was heated in a closed tube at 135 to 140° C. for 8 hours 11.7 per cent of the weight of the pentose was converted into furfural. Xylose heated in a closed tube with 10 per cent acetic acid solution and 10 per cent formic acid showed a fufural conversion of 31.32 per cent, and an increase in the temperature for the concentration of the acids resulted in further increasing the amount.

Chemical utilization of southern pine waste, M. C. WHITAKER and J. S. BATES (*Jour. Indus. and Engin. Chem.*, 6 (1914), No. 4, pp. 289-298, figs. 4).—This is an investigation of methods of utilizing southern pine waste (not convertible into lumber) with regard to obtaining turpentine, rosin, and pulp in marketable form.

The possibilities of hardwood distillation on the Pacific coast, R. C. PALMER (*Metallurg. and Chem. Engin.*, 12 (1914), No. 10, pp. 623-626).—A description of the hardwoods available on the Pacific coast for preparing tanning materials and the manufacture of products of destructive distillation (alcohol, acetate of lime, and charcoal). The cost of building a plant and the marketing of the products are considered.

Chemistry of the sugar industry, O. WOHRZYK (*Chemie der Zuckerindustrie. Berlin, Julius Springer, 1914, pp. XVI+676, figs. 18*).—This text and handbook is divided into three parts, viz, the chemistry of the beet, the chemistry of raw sugar manufacture, and the chemistry of sugar refining. It contains 159 tables and an appendix which deals with pure chemistry, especially with relation to the interpretation of the contents of the book.

Progress made in the manufacture of beet sugar in 1913, E. O. VON LIPPMANN (*Chem. Ztg.*, 38 (1914), No. 10, pp. 97-100).—A retrospect of the advances made in the agriculture, chemistry, and commerce of the beet-sugar industry in 1913.

METEOROLOGY.

What the Weather Bureau is doing in agricultural meteorology, P. C. DAY (*Internat. Inst. Agr. [Rome], Mo. Bul. Agr. Intel. and Plant Diseases*, 6 (1915), No. 5, pp. 649-652).—After briefly defining "the new science of agricultural meteorology" and indicating its importance, this article notes the ways in which the Weather Bureau of the U. S. Department of Agriculture is endeavoring to develop this field of investigation and what it is now doing to aid the agricultural interests of the country.

It is stated that although the bureau's chief effort and success lie in the prevention of crop loss by timely warnings of adverse weather conditions, it has actively entered, in cooperation with other bureaus of the Department and the state agricultural colleges and experiment stations, into investigations having as their object "the complete correlation of climate and plant growth." Among the lines of work of direct value to the farmer in which the bureau is now engaged are the distribution of frost warnings in fruit growing and trucking regions, measurements of snow in the western mountain States as a basis for predicting the probable water supply for irrigation, distribution of information regarding pasture conditions on the ranges with a view to bringing about a favorable distribution of cattle, warnings of adverse weather conditions in the great corn, wheat, cotton, tobacco, sugar, rice, and truck-growing regions, and studies on the occurrence and distribution of frost in mountain regions, with particular reference to the location of orchards.

Drought frequency during crop-growing season (*U. S. Dept. Agr., Nat. Weather and Crop Bul.* 7 (1915), p. 6).—A map is given showing the frequency of droughts (period of 30 consecutive days or more in which the precipitation

did not amount to 0.25 in. in any 24 hours) during the last 20 years, for the period from April to September, inclusive. The greatest frequency is recorded for the Great Plains area and the least in the southern Appalachians.

Meteorological reports, C. C. GEORGESON (*Alaska Stas. Rpt. 1914, pp. 89-96*).—Tabular monthly summaries are given of observations on temperature, precipitation, and condition of the weather at 25 stations in different parts of Alaska during 1914.

Australian rainfall, H. A. HUNT (*Rpt. Brit. Assoc. Adv. Sci., 1914, pp. 439-442*).—This article deals with the controlling causes and distribution of rainfall in Australia. The relation of the southeast and westerly trade winds, the monsoonal and southern depressions, cyclones and anticyclones, and physical features of the country to the distribution of rainfall is considered in detail.

It is shown that the isohyets describe somewhat concentric curves around the central dry area of Australia, such modifications as occur being due mainly to variations in elevation. During the hot season, from November to April, inclusive, the northern parts of Australia are wet and the southern dry, the reverse being true during the colder months, May to October. In the eastern areas of the continent, however, the rainfall is distributed fairly generally throughout the year. Occasionally there are heavy monsoonal rains in the interior, resulting in luxuriant growth of grass and herbage. The heaviest rainfall recorded occurs at Innisfail on the northeast coast of Queensland, where the average annual rainfall is 145 in., the maximum being 211.24 in., and the minimum 69.87 in. The driest region for which records are available lies east and northeast from Lake Eyre, where the average annual rainfall is less than 5 in. This is also the region of lowest elevation, Lake Eyre being 39 ft. below sea level. The interior of Australia, which is usually considered the driest region, has, as far as available records show, an annual average rainfall of from 10 to 12 in. It is stated that wheat growing is safe with 10 in. of rainfall from April to October, inclusive.

In general it appears that the rainfall of Australia is usually ample for pastoral and agricultural industries over two-thirds of its area. The different regions have distinct seasonal dry and wet periods, and the country is subject in part, but never in whole, to prolonged periods when the rainfall is below the seasonal average.

“There exists apparently an oscillatory movement of the seasonal rains throughout Australia about a center in the vicinity of Forbes, in New South Wales.” Apparently the seasonal rains in Australia are more regular than has generally been supposed, and the alternating dry and wet seasons are quite definitely defined.

The ten-inch line of rainfall, T. CHERRY (*Rpt. Brit. Assoc. Adv. Sci., 1914, pp. 645, 646*).—From a study of the rainfall and the practice of dry farming in the southern third of the continent of Australia the conclusion is reached that dry farming does not begin until the 15-in. line of rainfall is passed, the winter and the total rainfalls being nearly identical. It is stated that “the experience of the last 15 years has shown: (1) That with the assistance of small amounts of soluble phosphates profitable crops may be grown on less than 10 in. of winter rainfall. (2) Provided the land is fairly fertile rapid growth takes place in July and August, so that a considerable margin is available in autumn for early and late planting. (3) The dry weather toward harvest time materially reduces the risk from all fungus diseases in cereals. (4) Wherever wheat can be grown peas may also be grown if necessary as an alternate crop. (5) Evaporation in winter is comparatively small, and consequently by fallow-

ing and other modern methods a payable crop is obtained on a lower rainfall than is the case in any other part of the world. (6) The slight ground frosts which often occur in the winter nights appear to simulate the growth of the cereals when followed by 10 hours of bright sunshine. (7) The chief problem which has now to be solved is to devise methods by which large numbers of sheep and cattle can be profitably kept on the wheat farms in the 10-in. rainfall regions. (8) Lands originally covered with scrub and producing very little grass have been proved to be very suitable for wheat. With the gradual advances in the numbers of stock kept on these farms permanent agricultural settlement is likely to extend well beyond the 10-in. line of rainfall."

The influence of weather conditions upon the amounts of nitric acid and of nitrous acid in the rainfall near Melbourne, Australia. V. G. ANDERSON (*Rpt. Brit. Assoc. Adv. Sci., 1914, pp. 338, 339*).—A previous article based upon the observations here briefly reported has already been noted (E. S. R., 31, p. 812).

The influence of weather conditions upon the amounts of nitric acid and of nitrous acid in the rainfall at and near Melbourne, Australia. V. G. ANDERSON (*Quart. Jour. Roy. Met. Soc. [London], 41 (1915), No. 174, pp. 99-122, figs. 11*).—The amounts of nitrous and nitric acids were determined in the rainfall at the center of Melbourne and at the suburb of Canterbury six miles distant during 16 months beginning November 1, 1912, as previously noted (E. S. R., 31, p. 812). The nitrous acid was determined by a modification of the method of Griess and the nitric acid by the salicylic acid method of Caron and Raquet (E. S. R., 25, p. 613).

Correlation of the data with the meteorological elements of Melbourne and with the daily isobaric charts of Australia showed "the existence of a relation between weather conditions and the amounts of the nitrogen acids in the rainfall. . . . A relation between atmospheric temperature and the ratio of nitric nitrogen to nitrous nitrogen was observed, and according to the results it seems probable that, in rain water, nitric and nitrous acids are formed in equal molecular proportions, and that the effect of variations in temperature is to change the velocity of transformation of nitrous acid into nitric acid, resulting in a high ratio in summer and a ratio approaching unity in winter. . . . For a given type of weather, and in samples of rain water collected during 24 hours (a) the concentration of oxidized nitrogen varies inversely as the rainfall, and therefore (b) the product of the concentration of oxidized nitrogen and the rainfall is constant. . . . Amounts (pounds per 1,000 acres) of oxidized nitrogen per day varying from 1.5 in the case of certain antarctic storms to 35 in the case of intense tropical storms" are reported.

In the discussion following the paper especial emphasis was laid on the importance of determining the amounts of ammonia as well as of nitrous and nitric acids in the rainfall.

SOILS—FERTILIZERS.

Thirty-nine experiments in soils, C. L. QUEAR (*Muncie, Ind.: Author, 1915, pp. 90, figs. 15*).—In this publication 39 soil experiments and 13 supplementary experiments are outlined for the use of beginners in the study of agriculture.

Surface formations and agricultural conditions of northwestern Minnesota, F. LEVERETT and U. G. PURSELL (*Univ. Minn., Geol. Survey Bul. 12 (1915), pp. VI+78, pls. 8, figs. 14*).—This report describes the topography, geology, and climate of northwest Minnesota, and deals at length with the soil and agricultural conditions and land classification by counties. ✓

Fruit soils in the Sierra foothills, J. W. NELSON (*Mo. Bul. Com. Hort. Cal.*, 4 (1915), No. 3, pp. 134-139).—This article deals briefly with the soils of an area of about 5,000,000 acres in the Sierra foothills of California, the topography of which consists of a series of low broken hills, small narrow valleys, rounded ridges, and moderate to steep slopes along the valley margin. The drainage is good except in small irrigated valleys.

The soils are prevaillingly red in color and have been derived mainly from igneous and metamorphic rocks. It is stated that they are generally fertile and their greatest requirement appears to be organic matter. They are all well supplied with mineral plant food, but the heavier types rank first and are the most durable soils.

It is also stated that the marked variation in elevation, rainfall, temperature, and soils makes the growth of a wide range of profitable fruits possible in this belt.

The atmosphere of the soil: Its composition and the causes of variation, E. J. RUSSELL and A. APPELYARD (*Jour. Agr. Sci. [England]*, 7 (1915), No. 1, pp. 1-45, figs. 17).—This article, the first of a series, reports investigations of the composition and characteristics of the soil air.

It was found that the free air in the pores of the soil to a depth of 6 in. is very similar in composition to the atmospheric air, but differs in that it shows greater fluctuations in composition and contains more carbon dioxide and correspondingly less oxygen, the average in 100 volumes being 0.25 volume of carbon dioxide and 20.6 volumes of oxygen against 0.03 volume of carbon dioxide and 20.96 volumes of oxygen in atmospheric air. "Usually the sum of the CO₂ and oxygen is only slightly less than in atmospheric air, but at periods when nitrates rapidly increase there is a perceptible falling off of oxygen and a still greater one in waterlogged soils."

In addition, there is another atmosphere dissolved in the water and colloids of soils which consists mainly of carbon dioxide and nitrogen and has practically no oxygen. "The fluctuations in composition of the free soil air are mainly due to fluctuations in the rate of biochemical change in the soil. . . . The rate of biochemical activity attains a maximum value in late spring and again in autumn and minimum values in summer and winter. In autumn the bacteria increase first, then the CO₂ rises, and finally the nitrate increases. From November to May . . . the soil temperature . . . appears to be the dominating factor, from May to November . . . the rainfall and to a less extent the soil moisture. . . ."

"It is shown that the dissolved oxygen brought in [in rainfall] is probably a factor of considerable importance in renewing the dissolved soil atmosphere and facilitating biochemical change. . . . No evidence could be obtained that the growing crop markedly increases the amount of CO₂ in the soil air, and if it gives rise to any great evolution of CO₂ in the soil, it apparently exercises a corresponding depressing effect in the activities of soil bacteria. . . . As the soil differences are eliminated so the differences in composition of the soil air become less and less. . . . Such weather conditions as barometric pressure, wind velocity, variations in temperature from the mean, small rainfall, etc., seem to have but little effect on the soil atmosphere."

A manometer method of determining the capillary pull of soils, W. A. CANNON (*Plant World*, 18 (1915), No. 1, pp. 11-13).—An apparatus for determining the capillary lift of soils is briefly described.

It consists essentially of a U-shaped mercury manometer with open ends, a soil container of 500 cc. capacity, and a water reservoir of about 500 cc. capacity. The water reservoir is connected by means of a T-shaped glass tube

and rubber tubing to the manometer and the soil container. The flow of water from the reservoir to the soil container is regulated by stopcocks and the capillary lift of the soil is indicated by the rise of the mercury in the manometer.

Losses of moisture and plant food by percolation, G. S. FRAPS (*Texas Sta. Bul. 171 (1914)*, pp. 5-51).—The results of three years' experiments made to ascertain the amount of percolation and evaporation from eight different soil types of Texas and the effect of cultivation, manure, and fertilizers upon the amount of water percolating and on the losses of plant food therein are reported. The soils used were Norfolk sand, Orangeburg fine sandy loam, Houston loam, Houston black clay, Yazoo clay, Miller fine sandy loam, Crawford clay, and Lufkin fine sandy loam.

Percolation was found to be greater through uncultivated clays and loams than through uncultivated sands and sandy loams. Cultivation increased percolation through the latter, but had little effect upon the former. Potassium sulphate and manure increased percolation through sandy soils but the former decreased percolation through clay soils. The fall application of manure was more effective in increasing percolation than the spring application.

The amount of nitrates in water percolating from uncultivated soils was related to a certain extent to the total nitrogen of soil and subsoil. More nitrate appeared in the percolates from manure applied in the fall than in the spring. An application of sodium nitrate increased the nitrates in the succeeding percolates of two of the soils, but with the other six no effect was observed until three or four weeks later. Only small quantities of potash appeared in the percolates from most of the soils, even after heavy applications of potash were made, the maximum loss being 12 per cent in three years from the Norfolk sand and the losses from the other soils varying from 0 to 4.5 per cent. From 9.7 to 66.6 lbs. of potash per acre per year were lost by percolation from uncropped, uncultivated, and unfertilized soils, and the losses were to a certain extent related to the active potash of the soil. The losses of phosphoric acid in the percolates were very small, but the losses of lime were large, varying from 70 to 582 lbs. per acre from the uncropped, uncultivated soils. The lime losses were in a general way related to the quantity of lime soluble in strong hydrochloric acid.

Effect of moisture content of a sandy soil on its nitrogen fixing power, C. B. LIPMAN and L. T. SHARP (*Bot. Gaz.*, 59 (1915), No. 5, pp. 402-406).—Studies of the natural nitrogen fixing flora of a light sandy soil from a walnut grove with reference to moisture content are reported. The soil-culture method was used.

It was found that nitrogen fixation in this soil by means of its natural flora and under optimum temperature conditions takes place most actively with a water content varying from 20 to 24 per cent, based on the air-dry weight of soil. With 28 per cent of moisture there was a slight decline in nitrogen fixation. With 32 per cent a marked decrease in nitrogen fixing power of the soil was evident, and a still greater decrease was noted with 36 per cent. Almost no nitrogen fixation, or very little, took place with a moisture content of 4 per cent (air-dry basis), but a very marked increase occurred when 8 per cent was present, and amounts of moisture equivalent to 12 per cent (air-dry basis) gave about the same nitrogen fixation as 32 per cent moisture.

It is concluded from these results that for the soil used the aerobic forms of nitrogen-fixing bacteria do best with a 20 per cent moisture content. At higher percentages of moisture up to 24 per cent the anaerobic forms become much more active, while the aerobic forms are depressed in their nitrogen-fixing powers.

The effect of some organic soil constituents upon nitrogen fixation by *Azotobacter*, H. S. REED and B. WILLIAMS (*Virginia Sta. Tech. Bul. 4 (1915)*, pp. 81-96; *Centbl. Bakt. [etc.]*, 2. Abt., 43 (1915), No. 1-7, pp. 166-176; *abs. in Science, n. ser.*, 42 (1915), No. 1079, pp. 320, 321).—The results of a study of the effect of various organic compounds likely to be constituents of the soil on the growth of *Azotobacter* are reported, which indicate that nitrogen fixation by these organisms was only slightly influenced by most of the compounds tested. A depression was noted in a number of cases, but it was usually the result of a relatively high concentration of the compound used. Hydroquinone and salicylic aldehyde were the most toxic of any compounds studied, while esculin, quinic acid, and borneol afforded marked stimulation to the growth of the organisms. In concentrations which are considered fatal to certain higher plants many of the compounds only slightly depressed fixation.

Such nitrogenous compounds as nicotin, picolin, guanidin, and skatol showed toxic properties commensurate with those usually ascribed to these substances, while caffein appeared to stimulate the growth of the organism. "Many of the nitrogenous compounds used which have been reported as beneficial to higher plants exercised a marked depression on fixation. It appears that the simpler compounds were more pronounced in this respect than were the more complex ones. It is suggested that this condition is not one of toxicity, but that the nitrogen of the compounds was utilized by *Azotobacter* in preference to that of the atmosphere. Urea, glycocoll, formamid, and allantoin were especially active in depressing fixation."

A list of the organic compounds studied, showing their occurrence and possible source in the soil, together with reports on their action toward higher plants and a list of references to literature bearing on the subject, are appended.

Nitrogen fixation and nitrification in various soil types, H. S. REED and B. WILLIAMS (*Virginia Sta. Tech. Bul. 3 (1915)*, pp. 59-80).—This bulletin reports in four papers experiments on the effect of mineral fertilizers on nitrogen fixation and nitrification in soil, nitrogen fixation and nitrification in various soil types, and the effect of sand and lime on nitrification.

It was found that the various inorganic fertilizers did not cause marked stimulation of nitrogen fixation in truck soils. The maximum fixation was attained under the influence of stable manure with lime.

Crimson clover increased the nitrifying power of the soil 83 per cent, crimson clover and lime 526 per cent, stable manure 120 per cent, and stable manure and lime 407 per cent.

An examination of 93 soils, 88 of which were collected in pairs of virgin and cultivated samples, showed the superiority of cultivated soils for nitrogen fixation. Fixation by virgin clay soils was greater than by light virgin soils. The results of these studies are taken to indicate that, with the possible exception of lime, the humus content of a soil and its cultivation are the only factors which materially affect nitrogen fixation.

In nitrification studies of the 93 soils, using ammonium sulphate solution, it was found that cultivated soils showed decidedly higher nitrifying qualities than the virgin soils. The nitrifying power of light open sandy soils was strikingly low, that of loams and clay loams was the highest, and that of heavy clays was also low, but not so low as that of the light soils. It is thought, however, that the low nitrifying power of the heavy clays can be improved by proper tillage.

Studies of the soils with reference to their accumulation of nitrates over a period of six months did not show the distinctive superiority of cultivated soils over virgin soils, as was evinced in the ammonium-sulphate tests. The clay

loam failed to show nitrifying powers commensurate with those shown with ammonium sulphate, although the relationship as regarded other soil types was quite consistent in both series.

In tests of the effect of sand and lime on nitrification in heavy clay soils, a sandy loam, and a light porous soil it was found that lime caused a marked increase in nitrates, while sand failed to stimulate nitrate formation, particularly in the clay soils.

The organic nitrogen of Hawaiian soils, W. P. KELLEY and ALICE R. THOMPSON (*Jour. Amer. Chem. Soc.*, 36 (1914), No. 2, pp. 429-444).—Brief technical accounts are given of investigations more fully reported elsewhere (E. S. R., 30, p. 419; 31, p. 11).

Notes on some methods for the examination of soil protozoa, C. H. MARTIN and K. R. LEWIN (*Jour. Agr. Sci. [England]*, 7 (1915), No. 1, pp. 106-119, pls. 2).—The purpose of this paper is to outline the present knowledge of the life of the protozoa in the soil and to describe certain methods which have been found useful in work on the subject.

The authors think it probable that there are always some free living protozoa present in an active state in even relatively dry, poor soils. "In manuring on ordinary soil with farmyard manure a large number of protozoa are introduced into that soil, and if the conditions of culture are such as to necessitate a high water and a high manurial content the protozoa may well get the upper hand to such an extent as to produce a well-marked deleterious effect on the crop, resulting in the condition known as soil sickness. . . . The nature of the protozoan fauna seems to vary to a certain extent with the soil under examination. . . . It is probably that the richer the soil and the higher the water content at the time of examination, the greater the probability of the dominant culture form being the dominant trophic form in the fresh soil. . . . Up to the present the dominant active fauna of the soil, as shown by the fresh films, consists mostly of amœbæ, the cœcæbe, and small flagellates. . . . In this connection one point which requires further investigation is the frequent prevalence of relatively large flagellates in soil culture (e. g., *Prowazekia* and *Copromonas*), whereas in fresh films the only flagellates found are very small monads. . . .

"Another factor which must be reckoned with . . . is the possibility that the present methods for the examination of fresh soil films do not give a fair account in regard to these large flagellates, which may be caught up by their flagella amongst the soil particles."

It is stated in conclusion that there appear to be three categories under which the protozoan population of any soil at a given moment should be studied, i. e., (1) the active fauna, (2) the cysts, and (3) the cultural fauna. "In the immediate future better methods must be devised for the detection of the active fauna, a complete study is needed of the possible seasonal variations which might result in a transfer of certain forms from the resting fauna to the active fauna, and a more careful study must be made of cultural conditions, so that it may be possible to cultivate at once any desired member of the active fauna of a soil."

Studies on soil protozoa, A. CUNNINGHAM (*Jour. Agr. Sci. [England]*, 7 (1915), No. 1, pp. 49-74).—The work discussed in this paper is a continuation of that previously reported (E. S. R., 31, p. 26) and deals with (1) the dilution method and its application to the enumeration of protozoa in soils, (2) the effect of protozoa on the numbers of bacteria in ammonifying solutions and on ammonification in solution tests, and (3) the effect of inoculations of protozoa on the bacterial content of partially sterilized soils.

It was found that the dilution method gives only relative, not absolute, results, and that the whole of the protozoa in soils do not develop in soil extract. In connection with the dilution method, heating to 58° C. appeared to kill a number of the encysted protozoa in addition to active forms. Treatment with caustic potash killed all active protozoa, but left the encysted uninjured. "It is evident that it is impossible to fix upon a temperature which will destroy all active protozoa in soils and leave the cysts perfectly uninjured. . . . As it is better to select a temperature which will kill all active forms even if it does injure some of the cysts, rather than one which will leave the cysts unharmed, and also probably some of the active forms alive, the continued use of 58° C. seems to be justified."

Experiments on the effects of temperature and moisture on the soil protozoa brought out "that some, at least, of the protozoa in soils lead an active life and are capable of multiplying to quite a considerable extent when the conditions become favorable." It was also found that the soil protozoa, in solutions, exercise a very decided limiting effect on the numbers of bacteria.

The results obtained as regards the influence of protozoa on ammonification in solution tests were inconclusive.

The reduction in bacterial numbers in the soils inoculated with protozoa was found to be very marked and to lie well outside the limits of experimental error. "The conclusion may safely be drawn, therefore, that the limiting factor, or at least one limiting factor (of Russell and Hutchinson) has been inoculated into the sterilized soils and has produced its effects on the numbers of bacteria. . . . As it has been shown that the protozoa are capable of reducing the numbers of bacteria in solutions, it appears justifiable to consider them as the limiting factor in soils."

Studies on the lime requirements of certain soils, H. B. HUTCHINSON and K. MACLENNAN (*Jour. Agr. Sci. [England]*, 7 (1915), No. 1, pp. 75-105, pl. 1, figs. 4).—In continuation of work along the same general lines as that previously noted (E. S. R., 32, p. 32), investigations are reported dealing with the determination of the amount of lime (CaO) necessary to induce partial sterilization changes in soils and the amount of lime (CaO) or chalk (CaCO₃) required for soil neutralization.

It was found that calcium oxid is capable of producing partial sterilization effects but that calcium carbonate is not. The amounts of lime necessary to produce specific effects in different soils varied greatly, and the critical amount required was found to depend on the amount necessary for the production of an alkaline reaction of the soil water. The results obtained on this basis, correlated with those of pot experiments, showed that the amount indicated coincides with that required for the maximum production of dry matter in the first crop following treatment and the maximum production of dry matter in the first four crops. Applications of lime double or treble the amount indicated by the method, although causing an increase in the ammonia and nitrates produced, did not give corresponding increases in crop. Certain physical changes also occurred about the partial sterilization point.

The determination of the lime requirements of the soil was found to depend on the absorptive capacity of the soil for calcium carbonate (present in solution as bicarbonate). Comparative tests of various soils to which quantities of lime had been added previously showed a proportionate diminution of the lime requirements, and no absorption was indicated in the case of neutral soils. Soils showing a positive lime requirement according to this method were found to respond distinctly to the application of carbonate by increased ammonia and nitrate production in laboratory experiments and by greater plant growth in

pot culture and field work. The application of lime to field soils was reflected in decreased lime requirements and increased crop production even after a prolonged period (upwards of 17 years). The values of calcium oxid and carbonate were found to be identical, provided the lime requirements (for neutralization purposes) were not fully satisfied. After the neutral point was reached calcium oxid exercised its specific effect. An application of carbonate to a soil accelerated the process of ammonification and nitrification to a lesser degree. "The results of an acidity, or lime requirement, test and not those of determinations of free carbonate should be taken into consideration when the needs of any particular soil are concerned. In the case of soils on the same geological formation a definite relation between soil reaction and natural flora has been traced. The occurrence of certain plants on acid soils appears to be determined by their capacity of resistance to acidity."

A list of references to literature bearing on the subject is appended.

Probable combination of the chlorin ions in alkali salts, R. F. HARE (*New Mexico Sta. Bul. 95 (1915), pp. 3-6*).—Experiments showing the effect of heat on chlorids in the residue from some New Mexico irrigation waters and showing the loss of chlorids on heating 0.5 per cent solutions of magnesium chlorid, calcium chlorid, and sodium chlorid singly and in different mixtures are reported. The results are taken to indicate "that heating the residue of chlorids from a water or soil solution at a low red heat for ten minutes might furnish a method for determining the chlorin in mixed alkali salts that exist in combination with magnesium."

The effect of arsenite of soda on the soil, W. T. MCGEORGE (*Hawaii Sta. Press Bul. 50 (1915), pp. 16, figs. 3*).—Investigations on the effect of sodium arsenite on the growth of millet, cowpeas, and buckwheat and on the physical, chemical, and biological activities in heavy red clay, brown clay, and highly organic silt soils are reported.

It was found that the effect of sodium arsenite on plant growth depends upon the resisting power of the plant and upon the chemical and physical nature of the soil. In small quantities plant growth was stimulated in most instances, but when added at the rate of 0.1 to 0.25 per cent plant growth was made practically impossible. Sodium arsenite materially altered the mechanical condition of the soil, its action being primarily that of a deflocculating agent, thus checking the movement of the water.

The influence of sodium arsenite on ammonification and nitrification varied considerably in the different soil types, and no general rule applicable within reasonable limits was established.

Sodium arsenite was strongly fixed by the soil, even resisting the washing of heavy rains, and accumulated in the top layer. An analysis of a sample of soil from a tract of land sprayed three times a year for five years at the rate of 5 lbs. of sodium arsenite per acre per application showed all the arsenic to be present in the top 4 in. of soil.

The influence of zinc vessels in culture experiments, K. GHEDROIZ (*Selsk. Khoz. i L'isov., 345 (1914), July, pp. 625-627; abs. in Internat. Inst. Agr. [Rome], Mo. Bul. Agr. Intel. and Plant Diseases, 6 (1915), No. 1, pp. 57, 58*).—Pot experiments during three years showed that the sulphate and chlorid of zinc had almost the same effect on the growth of mustard. The effect on barley differed from that observed in the case of mustard, as with 0.02 per cent of zinc the growth of mustard ceased, while barley gave a relatively good yield. Zinc in very small quantities, however, stimulated the growth of mustard, but had a depressing effect on barley.

Long-continued experiments with zinc pots showed that red clover grown in acid soils lost its germinating power and made feeble growth in the third year. The injurious effect of the zinc pots was apparent in the case of clover in the second year. It was most pronounced in the case of acid soils.

The effect of fertilizers and stimulants upon the growth and production of *Corchorus capsularis*, S. F. ALBANO (*Philippine Agr. and Forester*, 3 (1915), No. 9-10, pp. 218-226).—Experiments on jute with cow manure, kainit, and tankage, with or without the addition of potassium sulphate, are reported. A beneficial effect from the use of fertilizer was observed in the growth of the plant and in the yield of fiber. The best results were obtained with mixtures containing nitrogen.

In comparative tests of the effect of dilute solutions of borax and salts of manganese, mercury, iron, calcium, nickel, zinc, fluorin, and iodine it was found that jute "is decidedly less subject to stimulation with various chemicals than are some of the other crops with which experiments have been carried on, most notably, for instance, potatoes and radishes. The only chemicals whose use can be recommended as very likely to be profitable as a result of these tests are iron and very dilute nickel."

Various forms of dung, D. A. GILCHRIST (*Armstrong Col. Newcastle-upon-Tyne, Agr. Dept. Bul. 10 (1914)*, pp. 10, 11; *abs. in Nature [London]*, 94 (1915), No. 2363, p. 651).—Fresh dung, dung kept just long enough to be in good condition for application, and old dung stored in the heap for some months were applied at the rate of 12 tons per acre in five 4-course rotations of swedes, barley, hay, and oats. The manure which had been kept just long enough to be in good condition gave the best results.

Green manuring table, F. ARNDT (*Deut. Landw. Presse*, 42 (1915), No. 29, p. 255).—A table is given showing for German conditions the quantities needed for different purposes and the cost of different green manures.

German nitrogen monopoly (*Chem. Ztschr.*, 14 (1915), No. 5-6, pp. 17, 18).—The terms of the German Imperial monopoly on nitrogenous materials used for fertilizing purposes, which is to be effective until March 31, 1922, are explained.

Lime nitrogen, R. KINDLER (*Illus. Landw. Ztg.*, 35 (1915), No. 3, pp. 11, 12).—This is a concise summary of present knowledge regarding the nature and value of lime nitrogen as a fertilizer.

Cyanamid in complete fertilizer mixtures, E. J. PRANKE (*Com. Fert.*, 10 (1915), No. 2, pp. 15, 16).—It is pointed out in this article that the quantities of cyanamid used by King in experiments previously noted (*E. S. R.*, 33, p. 25) were out of proportion to the amounts of fertilizer mixture and of acid phosphate used. It is considered advisable to limit the use of cyanamid to 60 lbs. per ton of fertilizer mixture containing approximately 1,000 lbs. of acid phosphate.

Phosphates in Massachusetts agriculture: Importance, selection, and use, W. P. BROOKS (*Massachusetts Sta. Bul. 162 (1915)*, pp. 130-167, pls. 2).—This bulletin reviews the Hopkins theory of permanent soil fertility and reports an extended study of the applicability of this theory, with particular reference to the use of phosphorus, to Massachusetts soils and agriculture.

It is shown that phosphoric acid is not relatively deficient in Massachusetts soils and that under the systems of agriculture common in the State, which usually include the use of some phosphate, there is no reason to believe that it is generally becoming more so. It is shown in fact that, contrary to the Hopkins theory, for most of the leading crops of the State potash is far more frequently the dominant food requirement than phosphoric acid.

The general results of two series of experiments comparing different phosphates, one extending over twelve and the other over eighteen years, are presented to show that the application of at least a moderate amount of phosphate is usually profitable and that the more soluble and available materials give results much superior to those obtained with the fine ground rock phosphates. The more soluble phosphates were found to favor more rapid early growth, earlier and more perfect maturity, and larger yields than the rock phosphates and to be used with greater profit.

On this basis Massachusetts farmers, gardeners, and orchardists are advised against the general use of raw rock phosphates. "The phosphates employed should be the more soluble and available kinds, such as acid phosphate (dissolved rock), dissolved bone, basic slag meal, and bone meals."

Phosphoric acid and potash fertilization in the spring, SCHNEIDEWIND (*Landw. Wchuschr. Sachsen, 17 (1915), No. 8, pp. 61, 62*).—Seven years' fertilizer experiments with potatoes and sugar beets, and with wheat and barley as second crops, with and without stable manure fertilization, are summarized to show that these crops, when growing on soil fertilized with stable manure, either need no additional phosphoric acid or much less than is needed when no stable manure is used. Also the after effects of stable manure fertilization are considerable, as is indicated by the superior yields and smaller additional phosphoric acid requirements of wheat and barley as second crops on soil fertilized with stable manure.

A general statement is included as to the forms of phosphoric acid and potash best adapted to different soils.

Potash salts, 1914, W. C. PHALEN (*U. S. Geol. Survey, Mineral Resources of the United States, Calendar Year 1914, pt. 2, pp. 9-33, pl. 1; Press Bul. 215 (1915), p. 4*).—This report gives statistics of potash salts and of materials entering into the fertilizer industry imported for consumption in the United States during 1914 and several preceding years, discusses briefly the work done in 1914 with a view to finding a domestic supply of potash, and gives data regarding foreign potash deposits, particularly those of Spain (*E. S. R., 33, p. 26*).

It is stated that the potash salts imported for consumption in the United States in 1914 was 485,818,459 lbs., valued at \$3,743,973, a decrease in quantity and value as compared with 1913 of 126,696,457 lbs. and \$2,061,747, respectively. No especially notable developments in the discovery of new sources of potash with the object of establishing a domestic potash industry are reported.

In addition to potash salts, bone dust, calcium cyanamid, guano, basic slag, and other materials used as fertilizer, including kainit and manure salts, were imported in 1914 to the extent of 761,896 long tons, valued at \$9,921,439, and sodium nitrate valued at \$15,204,539.

A bibliography of papers on potash salts appearing during 1914 is given.

Radium fertilizer in field tests, C. G. HOPKINS and W. H. SACHS (*Science, n. ser., 41 (1915), No. 1063, pp. 732-735*).—This is a brief article based mainly upon experiments reported in more detail elsewhere (*E. S. R., 32, p. 821*), calling attention to the fact that the amount of radium which can be applied even at a cost of \$100 per acre is so small that it does not and can hardly be expected to produce any effect upon crop yields.

A municipal fertilizer plant at Los Angeles, California, B. A. HEINLY (*Engin. News, 73 (1915), No. 22, pp. 1063, 1064*).—Three plants built and operated by the park department of Los Angeles for the production of manure compost are described.

In these plants stable manure is allowed to ferment in a concrete-lined pit at a temperature of about 100° F. for from 20 to 30 days. It is then forked over, spread out in layers 1 ft. thick, to which 5 per cent by volume of wood ashes and 2 per cent of slaked lime are added, and the mixture covered with a layer of loam soil ranging from 50 to 150 per cent of the total volume, depending upon whether the manure was pure or mixed with much straw. The heap is built up of alternate layers of this kind to a height of about 8 ft. and allowed to stand about 60 days to disintegrate.

It is stated that at the end of this time about 80 per cent of the material will pass through a $\frac{1}{2}$ -in. mesh. Material coarser than this is returned to the manure heap for further disintegration.

It is stated that from 8,000 to 10,000 cu. yds. of such fertilizer is now being manufactured per annum, at a factory cost of \$1.38 per cubic yard, any surplus over the needs of the department finding a ready sale at \$2 per cubic yard at the factory.

The international movement of fertilizers (*Internat. Inst. Agr. [Rome], Mo. Bul. Agr. Intel. and Plant Diseases, 6 (1915), No. 3, pp. 323-370*).—This review issued in March, 1915, "contains, as far as possible, final figures for the fertilizer production and trade in 1912 and 1913, together with provisional figures for 1914, according to the scheme outlined in the first number of the review which was published in September, 1914" (E. S. R., 32, p. 425). Two new tables have been added to those appearing regularly, one referring to the world's production of natural guano and the other to the production of superphosphate in the different countries. An estimate of the natural reserves of phosphates in the United States is also included. The report contains no figures relating to the production of potash salts in Germany.

A bibliography of 178 references to recent literature on the subject of fertilizers is appended to the detailed tables of production, imports and exports, consumption, and prices.

Importation of fertilizer materials, B. Y. ORDOÑEZ (*Rev. Asoc. Rural Uruguay, 44 (1915), No. 3, pp. 173-186*).—This article reviews the laws of Uruguay relating to trade in fertilizers and describes the official methods employed in inspection.

AGRICULTURAL BOTANY.

The measurement of electrical conductivity as a method of investigation in plant physiology, W. STILES and I. JÖRGENSEN (*New Phytol., 13 (1914), No. 6-7, pp. 226-242, figs. 5*).—Giving a partial review of the work already done by others toward making use of electrical conductivity measurements in questions of plant physiology, the authors report on the methods and results of their own studies in this direction. They hold it probable that (while use of these methods is still in its preliminary experimental stage) with further development of methods, electrical conductivity may afford a convenient and comparatively simple means of investigating certain classes of problems in plant physiology.

A bibliography is appended.

A new theory regarding the feeding power of plants, E. TRUOG (*Science, n. ser., 41 (1915), No. 1060, pp. 616-618*).—As a result of investigations on the feeding power of plants the author proposes the following hypothesis:

"Plants containing a relative high calcium oxid content have a relatively high feeding power for the phosphorus in raw rock phosphate. For plants containing a relatively low calcium oxid content the converse of the above is

true." A calcium oxid content of less than 1 per cent is considered relatively low, and corn, oats, rye, wheat, and millet belong to this class. A content of more than 1 per cent is considered high, and to this class belong peas, clover, alfalfa, buckwheat, and most of the species of Cruciferae. The author considers that the feeding power of a plant for an insoluble substance depends primarily upon two conditions, (1) the solubility of that substance in carbonated water, and (2) whether or not the plant removes from solution all the products of the solubility reaction in the proper proportion, so as to allow the solubility reaction to continue indefinitely.

The presence of inorganic iron compounds in the chloroplasts of the green cells of plants, considered in relationship to natural photosynthesis and the origin of life, B. MOORE (*Proc. Roy. Soc. [London], Ser. B, 87 (1914), No. B 598, pp. 556-570*).—The author discusses experimentation designed to throw light upon the processes taking place and the substances occurring in the wide hiatus between the simple colloidal molecules of inorganic iron salts or oxides in the solution or suspension, which, as shown by Moore and Webster (*E. S. R., 30, p. 129*), possess the power of synthesizing formaldehyde in the presence of carbon dioxide with sunlight as energy supply, on the one hand, and such a highly complex organic substance as chlorophyll, on the other. It is stated that inorganic iron salts and iron or aluminum hydrates in colloidal solution possess the power of transforming the energy of the sunlight into the chemical energy of organic compounds. Inorganic iron in crystalline or colloidal form is thought to be present in the colorless part of the chloroplast of the green plant cell in many plants. In the absence of iron the green coloring matter can not develop in the leaf, although the green coloring matter itself contains no iron. In the presence of sunshine the iron-containing substance of the chloroplast develops the coloring matter, so that this itself is a product of photosynthesis induced by the iron-containing compound.

It is held that these facts afford an explanation of chlorosis and of its cure by inorganic iron salts, and demonstrate that iron is a primary essential in photosynthesis and the production of chlorophyll. The iron-containing substances of the colorless portion of the chloroplast and the chlorophyll produced by them thus become associated in the functions of photosynthesis as a complete mechanism for energy transformation.

Nitrites in plants, K. ASO and T. SEKINE (*Bot. Centbl., Beihefte, 32 (1914), 1. Abt., No. 1, pp. 146, 147*).—The authors, noting the statement of Klein (*E. S. R., 30, p. 30*) regarding the absence of nitrites in underground portions of *Sagittaria sagittifolia*, report a study of cases in which nitrites were doubtless present, though in slight concentrations, in the shoot-like buds of this plant. The nitrites were supposedly produced either by physiological oxidation of amido acids or by reduction from nitrates.

Free nitrogen and higher plants, M. MOLLIARD (*Compt. Rend. Acad. Sci. [Paris], 160 (1915), No. 9, pp. 310-313*).—Reporting and discussing his own experimentation testing for an alleged capability of higher plants to utilize atmospheric nitrogen, as upheld by Mameli and Pollacci (*E. S. R., 25, p. 633; 31, p. 223*), the author concludes that *Raphanus sativus* does not utilize the free nitrogen of the air.

Studies on anthocyanin bodies, O. GERTZ (*Svensk. Bot. Tidskr., 8 (1914), No. 4, pp. 405-435, figs. 20*).—The author gives an account of his observations on the various forms, structures, locations, arrangements, etc., of anthocyanin bodies as studied in more than 40 plant species belonging to almost as many genera, with a discussion thereof and of some related literature, which is listed in this connection.

A new method of so-called water culture, II, L. HILTNER (*Prakt. Bl. Pflanzenbau u. Schutz, n. ser., 12 (1914), No. 5, pp. 49-55, figs. 2*).—These experiments, continuing those previously reported with serradella (*E. S. R., 28, p. 817*), show the value of rock phosphate in nutritive solutions for use in growing oats as preventive of dry spot and tipburn and also as supplementary to or as replacing other nutritive components.

Antagonism and balanced solutions, R. H. TRUE (*Science, n. ser., 41 (1915), No. 1061, pp. 653-656*).—The author discusses the terms antagonism and balanced solutions as used by a number of investigators and claims that there appears to be no reason to limit the use of the term balanced solutions as is commonly done.

On the osmotic pressure of the juices of desert plants, J. A. HARRIS, J. V. LAWRENCE, and R. A. GORTNER (*Science, n. ser., 41 (1915), No. 1061, pp. 656-658, fig. 1*).—A series of cryoscopic determinations on the spring flora of the vicinity of Tucson, Ariz., with comparisons on species of spring and early summer plants in the vicinity of the Station for Experimental Evolution on Long Island have been made to test the results given by E. and Hilda Drabble (*E. S. R., 18, p. 824*) and Fitting (*E. S. R., 25, p. 430*).

The authors were unable to find pressures as high as those described by Fitting, but they do not claim that they do not occur. Pressures of 10.5 atmospheres or lower were obtained for about 50 per cent of the Cold Spring Harbor series, whereas in the desert plants 50 per cent of the pressures were 15.7 atmospheres or higher.

Relations between osmotic pressure and regulation of stomata, W. S. ILJIN (*Bot. Centbl., Beihefte, 32 (1914), 1. Abt., No. 1, pp. 15-35, figs. 8*).—Reporting details of experimentation on the behavior of leaf stomata under varying conditions the author claims that stomatal regulation, which is related to transpiration conditions, shows also a close relation to change in starch content, and this in itself shows a close relation with variations in osmotic pressure.

Regulation of the stomata is dependent directly upon physiological processes. Variation in total water content in a plant acts as a stimulating factor, conditioning the activation of certain enzymes which determine the state of the starch material. Alternations of osmotic properties and of turgor also result, the latter influencing the degree of stomatal opening.

The changes observed are not purely mechanical, but dependent upon the activity of living protoplasts under the influence of external stimuli, for example, alterations or differences in intensity of illumination, which seem to affect the osmotically influential contents of the guard cells.

The problems in a comparative study of transpiration in plants, W. S. ILJIN (*Bot. Centbl., Beihefte, 32 (1914), 1. Abt., No. 1, pp. 36-65, figs. 27*).—Results of studies on various types of plants are given, but they are considered to show that it is not yet possible by a study of the transpiration curves alone to ascertain the degree of protection enjoyed by types biologically different. The present work aims not so much to give exact results for individual species or plants as to mark out lines along which study may proceed in order to ascertain which plants may be expected to survive under given conditions or to win out in competition.

Increased carbon dioxid concentration in relation to transpiration and development in plants, N. KISSELEW (*Bot. Centbl., Beihefte, 32 (1914), 1. Abt., No. 1, pp. 86-96, pls. 2, figs. 3*).—The author describes experimentation relative to the effects of increased carbon dioxid supply on plants somewhat similar to that reported by Brown and Escombe (*E. S. R., 14, p. 546*) and by Fischer (*E. S. R., 28, p. 837*). The results agreed with Fischer's conclusions, inasmuch

as a heightened content of carbon dioxide considerably accelerated and increased development in the plants employed.

The effects of high temperatures on leguminous seeds, F. NEUBERGER (*Kísérlet. Közlem., 17 (1914), No. 1, pp. 121-170*).—The author exposed seeds of several leguminous plants in dry air at temperatures of 50 to 130° C. for $\frac{1}{2}$ to 6 hours and in water at 45 to 100° C. for $\frac{1}{2}$ to 2 hours, and then tested them for germinability under favorable conditions.

It was found that in general the injurious effects of high temperature were increased by its elevation and its duration. Decrease of water content in seeds by artificial drying increased progressively the power of resistance to heat in dry air. This, however, ceased at 130° C., even for short exposures.

Water at a temperature above the maximum point for germination remained harmless to seeds therein only until the germination changes were started. Resistance varied even within species and is considered as largely an individual character. High temperature is thought to break down the enzymes connected with activity of germination.

A bibliography is given.

Death of young plants from heat, L. SCHUSTER (*Naturw. Ztschr. Forst u. Landw., 12 (1914), No. 8, pp. 377-379, figs. 2*).—Noting accounts of heat injury by von Tubeuf (E. S. R., 31, p. 343) and by Münch (E. S. R., 31, p. 348), the author describes the effects of heat combined with dryness of the soil on plantlets of *Cedrela odorata*, *Baphia kirkii*, and *Azacia euanzensis* in the neighborhood of Morogoro, German East Africa.

External and internal phases of the action of attenuated acid gases and smoke on plants, H. WISLICENUS (*Mitt. K. Sächs. Forstl. Versuchsanst. Tharandt, 1 (1914), No. 3, pp. 85-175, pls. 4, figs. 19*).—This is a somewhat extended account of the repetition of former work under improved conditions and of later work (E. S. R., 10, pp. 531, 644; 32, p. 524), bearing upon the effects of atmospheric pollution with smoke and gases from industrial plants, particularly in high attenuation, upon development and functioning in plants.

It is stated that highly attenuated sulphuric acid is markedly injurious to plants only when the leaves or needles are assimilating and in proportion to the intensity of that activity, this acid being then poisonous and a delicate indicator of photosynthetic activity. Light intensity and assimilative activity are the principal conditions, but others are discussed as modifying factors.

Forest injury from coal smoke, C. BALTZ (*Ztschr. Forst u. Jagdw., 46 (1914), No. 3, pp. 158-174*).—Summing up a discussion of work reported by Wieler (E. S. R., 31, pp. 322, 521) and others, the author states that smoke injury to forest growth near furnaces is due largely to the direct action of the acids resulting from the oxidation of sulphur dioxide.

The degree of injury depends largely upon the situation and configuration of the area affected. It is favored by the melting of snow, also by fog or slow falling rains, which absorb the acid and give it up to the foliage. The effect is greater in case of the younger parts. Conifers are more sensitive than deciduous trees.

Good cultural conditions are considered the best means of protection against a tendency to injury through the soil.

Physiological characters of plants, their variability and their relation to the theory of evolution, S. IVANOW (*Bot. Centbl., Beihefte, 32 (1914), 1. Abt., No. 1, pp. 66-80*).—From a study of the characters, particularly oil production, of several series of species, the author concludes that plant characters fall into two categories, namely, morphological (which depend more upon external conditions and by modification form new species) and physiological (consisting

in the capacity to form certain substances and showing less dependence upon external conditions).

At the limits of genera physiological characters are modified in a quantitative way, but slowly, probably not at all qualitatively. Species, as complex morphological and physiological characters, are established through a slow process of evolution. Variation and evolution of physiological characters are easier to understand from the Darwinian standpoint than from that of De Vries, according to the author.

It is held that a natural rather than a fortuitous systematic arrangement of vegetable oils should be recognized.

On the nature of mutations, R. R. GATES (*Jour. Heredity*, 6 (1915), No. 3, pp. 99-108, figs. 7).—Noting views which have been advocated regarding the origin and fundamental nature of mutations, the author discusses some characters of *E. lutea*, *E. gigas*, and *E. rubricalyx* in connection with their behavior in regard to inheritance of chromosome numbers and other characters.

It is claimed that any theory which will explain the origin of the *E. rubricalyx* character, which is claimed to be inherited in simple Mendelian fashion (unlike those of *E. lutea* or *E. gigas*), will explain also the origin of all Mendelian differences. It is held that, as a rule, simple Mendelian characters arise through alteration on the part of a chromosome analogous to the mutations known to occur in certain bacteria. This type of change is considered as sufficient to account for the origin of all mutations inherited in Mendelian fashion. The change is considered to be fundamentally chemical rather than morphological in its nature.

The author concludes in general that mutations, which are of many kinds and tend in many directions, furnish the material for real evolution. The manner of inheritance of a character is determined, or at any rate limited, by the manner of its origin, that is, by the nature of the germinal change by which it occurred. Just as there are different types of discontinuity in variation, so there are various methods of inheritance of the differences which thus arise, these methods depending on the basic nature of the original change.

Induced variations in chromogenesis, M. R. SMIRNOW (*Abs. in Science*, n. ser., 41 (1915), No. 1060, pp. 621, 622).—The author states that chromogenesis may be increased not only by growing the bacteria on more favorable media and environment, but also by the process of selection, transplanting each time from the portion of the culture or from a colony that shows the most pronounced pigmentation.

Chromogenesis is considered to be more or less closely associated with the metabolic activities of bacteria. It varies with the strain and is more or less dependent upon oxygen, temperature, and the medium used. An organism may produce more than one color at one and the same time, or it may produce different colors, depending upon the environment and the medium used, particularly the latter.

Influence of the concentration of the nutrient substrate upon microorganisms, ZAE NORTHRUP (*Abs. in Science*, n. ser., 41 (1915), No. 1060, pp. 620, 621).—The effect of liquefying and nonliquefying organisms on gelatin media containing different concentrations of gelatin was investigated. The size of the colonies was found to be inversely proportional to the concentration of the gelatin. This was especially marked in the case of the organisms which are most active in liquefying gelatin.

Halophytic and lime-precipitating bacteria, K. F. KELLERMAN and N. R. SMITH (*Abs. in Science*, n. ser., 41 (1915), No. 1060, p. 624).—The authors report that of approximately 70 cultures isolated from water from the Great Salt Lake and sea water from Florida and the Bahamas three types of organisms

were secured. *Pseudomonas calcis*, a new spirillum, and a new bacterium were isolated from the sea water, and closely similar varieties of species of Spirillum and Pseudomonas were found in water from the Great Salt Lake. Both in sea water and in the water of the Great Salt Lake these bacteria were found associated with the precipitation of calcium carbonate.

Bacteria of the colon type occurring on grains, L. A. ROGERS, W. M. CLARK, and ALICE C. EVANS (*Jour. Infect. Diseases*, 17 (1915), No. 1, pp. 137-159, figs. 3; *abs. in Science*, n. ser., 41 (1915), No. 1060, p. 624).—A study was made of gas production by 106 colon-like cultures from grains which showed that under controlled conditions these organisms could be divided into three physiological groups, cultures giving a low volume composed of carbon dioxide only, those giving a low volume and a carbon dioxide-hydrogen ratio of 1.06, and those having a high volume and a ratio varying from 1.9 to 2.9.

Two other groups differing in their gas ratio and fermentation reaction were made, but they included a relatively small number of cultures.

Chondriosomes and their significance, F. CAVERS (*New Phytol.*, 13 (1914), Nos. 3, pp. 96-106; 4-5, pp. 170-180).—The author gives a bibliographical review, from which it is evident that there is still difficulty in reaching safe conclusions regarding the nature of the so-called chondriosomes. The evidence as to the existence of true chromidia in plants is considered still somewhat scanty and unconvincing. It is admitted that thus far the study of chondriosomes has definitely solved few if any of the numerous questions it has raised, and that it still remains to be shown whether chondriosomes are really cell organs which, like the nucleus, persist from generation to generation with certain definite functions, or are merely artifacts.

FIELD CROPS.

[Report of the] department of agronomy, C. S. KNIGHT (*Nevada Sta. Rpt.* 1914, pp. 30-33).—The results of experiments in testing different dates for planting sugar beets showed the period from April 20 to May 20 to be the most propitious. When planted on dates later than June 1 the yields decreased from 12.54 to 4.74 tons per acre. In variety tests with potatoes the yields ranged from 2.67 to 9.81 tons of marketable tubers per acre. The results favored home-grown seed.

In variety tests with mangels the yields ranged from 18.5 to 27.8 tons per acre, swedes from 20.6 to 26.5 tons, corn for silage 16,170 to 25,795 lbs., wheat 1,980 to 2,520 lbs., oats from 1,780 to 2,430 lbs., barley 2,200 to 2,250 lbs., irrigated Siberian oats from 46.4 to 61.45 bu. per acre, and irrigated White Australian wheat 30.38 to 43.22 bu.

The results of the irrigation experiment with oats "indicate that the greatest production was received with two irrigations before and three after heading, while the heaviest yield per acre-foot of water was obtained with one irrigation before and one after heading. The yields per acre of oats of over 56 bu. with one irrigation before and two or three after heading also indicate that the oat crop can better withstand a slight shortage of water before than after heading."

The results of the irrigation experiment with wheat show that "the greatest production was received with two irrigations before and two after heading. The heaviest yield per acre-foot of water was obtained with one irrigation before and one after heading."

Report of [field crops] work at Fairbanks Station, J. W. NEAL (*Alaska Stas. Rpt.* 1914, pp. 44-48, 48-51, 52-54, pls. 3).—The performance of several

varieties of barley, oats, spring rye, spring wheat, and of buckwheat, winter rye, winter wheat, alfalfa, and red clover that seem to be suitable as grain and forage crops for that region is given. The cultivation of potatoes and general methods of cultivation employed at this station are described and the successful production of potatoes and turnips noted.

Report of [field crops] work at Rampart Station, G. W. GASSER (*Alaska Stas. Rpt. 1914, pp. 56-64, pls. 2*).—The successful season's growth of Grimm alfalfa, sand lucern, and Mongolian and Chernobial alfalfas; *Medicago falcata* and *Vicia cracca*; Semipalatinsk and Disco alfalfas; *Trifolium lupinaster*; and Gobi Desert and Obb alfalfas is noted. Descriptions of varieties of spring wheat, spring rye, winter wheat, winter rye, barley, oats, and potatoes are given.

[Report of field crops work at Kodiak Station], M. D. SNODGRASS (*Alaska Stas. Rpt. 1914, pp. 68-74, pl. 1*).—It is noted that on the ash-covered soils wheat and barley when seeded with oats made better growth than when seeded alone.

Nitrate of lime and nitrate of soda showed marked gains with oats, fair gains with wheat, and little effect on barley. Fish guano, muriate of potash, fish and bone, bone meal, double-manure salts, and sulphate of potash had little effect on any of these grains.

In testing cow kale as a crop for cattle feed it was shown that plants must be started in hotbeds and transplanted to heavily manured soil to be successful. Turnips and rutabagas are noted as making a fair growth. The slow, unsatisfactory growth and yield of several varieties of potatoes is noted. The season is stated as being favorable for general garden vegetables. The making of hay and silage from native bluetop grass and from oats is mentioned.

The restoration of vegetation on the volcanic ash-covered lands (E. S. R., 32, p. 31) was slowly secured by seeding grasses. The wild rye grass (*Elymus mollis*) and bluetop came up through the ash and provided excellent growth.

Crop-growing suggestions to dry land farmers, A. ATKINSON (*Montana Sta. Circ. 45 (1915), pp. 121-140, figs. 10*).—The author discusses breaking the sod, tillage following breaking, tillage after the first year, and crops for the dry land farm, and suggests methods of production for spring and fall cereals, flax, corn, alfalfa, sweet clover, brome grass, timothy, and clover.

An article on potatoes by O. B. Whipple and notes regarding crop rotation for dry-land farming are included.

Crop production in the Great Plains area: Relation of cultural methods to yields, E. C. CHILCOTT, J. S. COLE, and W. W. BURR (*U. S. Dept. Agr. Bul. 268 (1915), pp. 28, figs. 2*).—This bulletin presents a summary of the data given in detail in six bulletins already noted (E. S. R., 33, pp. 137, 230, 231, 232, and 332), and discusses the value of the methods of tillage employed with the different crops, upon which the following conclusions were based:

“Under the normal conditions prevailing in any part of the Great Plains for a term of 10 years on any type of soil represented at any of the stations, some crops can be produced at a profit when proper cultural methods are practiced, provided that the prices of labor and of farm produce bear the same relation to each other as those which have prevailed there during the last 10 years. No single crop tested in these investigations can be raised profitably in all parts of the Great Plains area on any type of soil by any cultural method so far tested. As forage crops of some kind can profitably be grown at all stations, they must occupy an important place in any system of farming adapted to the Great Plains. Sufficient live stock must be kept to convert these crops into finished products on the farm, and sufficient forage must be produced and stored during favorable seasons to carry the live stock through specially unfavorable seasons.”

Cereal experiments at the Williston substation, F. R. BABCOCK (*U. S. Dept. Agr. Bul. 270 (1915), pp. 36, figs. 11*).—Descriptions of the soil, weather conditions with meteorological data, and the experimental methods employed are given, followed by detailed results of experiments conducted in cooperation with the North Dakota Experiment Station with spring and winter wheat and with oats, barley, flax, and minor cereals, and including tabulated data on yields of the varieties used, in some cases additional data being given on growth and weight per bushel.

“Spring wheats have given better results than winter wheats. Except in the dry years, 1910 and 1911, the durum wheats have produced higher yields than the common spring wheats. Kubanka durum wheat (C. I. No. 1440) gave the highest average yield of all of the spring wheats tested from 1908 to 1914, inclusive, 29.9 bu. per acre. Power five wheat (C. I. No. 3697) stood second for the same period, producing 28.6 bu. per acre. The bluestem group has not yielded as well as the durums and fives, and the average weight per bushel has also been lower. Rate-of-seeding tests with bluestem spring wheat have indicated that the highest yields are obtained from sowing 4 pk. to the acre. The average yields from winter wheat are lower than those from the spring wheats, for winter wheat frequently winterkills. Sowing winter wheat in grain stubble or standing corn gives protection to the plants and reduces the loss from winterkilling.

“The best three varieties of oats for the seven years 1908 to 1914 are Abundance, with an average yield of 66.4 bu. per acre; Lincoln, 65.9 bu.; and Siberian, 64.5 bu. These are all midseason varieties. The late-maturing varieties, such as White Russian, and the very early varieties, Sixty-Day and Kherson, have yielded much less than the midseason varieties. Rate-of-seeding tests with Swedish Select oats indicate that the best yields are obtained by sowing from 4 to 6 pk. per acre.

“The 6-rowed group of barley has yielded better than the 2-rowed group. The highest average yield for the seven years (1908 to 1914), 39.9 bu., has been produced by the Williston No. 170 (C. I. No. 882), a strain of Manchuria barley.

“Flax is grown with some difficulty on ground that is infested with weeds. In the seven years that tests were made only four crops were harvested. The average yield of the highest producing variety for these four years was 16.2 bu. per acre from the North Dakota No. 1221 (C. I. No. 16). Emmer and spring rye have not given as high average yields as oats, barley, or wheat. Proso, grown in field plats from 1912 to 1914, inclusive, gave an average yield of seed per acre of 25 bu. Kursk millet, grown in a plat test in 1914, yielded 38 bu. of seed per acre.”

The effect of different methods of inoculation on the yield and protein content of alfalfa and sweet clover, A. C. ARNY and R. W. THATCHER (*Jour. Amer. Soc. Agron., 7 (1915), No. 4, pp. 172-185*).—This article gives results of the effect of different methods of inoculation on the crop as shown in the harvest two years after seeding. The methods include no inoculation, commercial culture applied to the seed, commercial culture applied to the soil, soil from an old alfalfa field, soil from an old alfalfa field plus two tons of limestone per acre, and no inoculation but two tons of limestone. The yields of dry matter per acre in three cuttings by the different methods were, respectively, 7,343, 7,750, 7,533, 7,969, 7,969, and 7,934 lbs., and the average protein content as 16.34, 16.4, 16.97, 17, 18.02, and 16.67 per cent.

The effect of inoculation of alfalfa with soil from a sweet-clover field is shown in yields per acre as follows: No inoculation (3 plats), 1,277, 1,683, and 1,293 lbs.; with sweet-clover soil, 3,028 lbs.; and with alfalfa soil, 3,022 lbs.

The protein contents were 12.6, 12.6, 12.73, 15.79, and 15.55 per cent, respectively.

The effect of inoculation of sweet clover with soil from alfalfa and sweet-clover fields was to produce enormous increases in the yield of dry matter and to reduce slightly the percentage of protein. There was a large increase in the yield of both tops and roots of alfalfa and sweet clover as a result of inoculation, and the gain in weight was an actual increase in dry matter per plant and not an increase in the number of plants growing upon a given area of soil.

In each individual case, with both alfalfa and sweet clover, the ratio of tops to roots was greater in the inoculated plot than in the untreated check plot.

Determinations were made of the percentage of total ash and of nitrogen, phosphorus, and potassium in the dry matter. The figures for total ash show a very remarkable effect of the inoculation in increasing the ash content of the roots and decreasing it in the tops of the plants. Other results are given below.

Effect of inoculation upon quantity of plant-food constituents in crops of sweet clover and alfalfa.

Crop.	Treatment.	Part of plants.	Plant-food constituents present in crop.					
			Nitrogen per square yard.	P ₂ O ₅ per square yard.	K ₂ O per square yard.	Nitrogen per acre.	P ₂ O ₅ per acre.	K ₂ O per acre.
Sweet clover.....	Inoculated.....	Tops.....	<i>Gm.</i> 10.05	<i>Gm.</i> 5.15	<i>Gm.</i> 2.98	<i>Lbs.</i>	<i>Lbs.</i>	<i>Lbs.</i>
		Roots.....	1.46	1.17	.45
		Whole plant.....	11.51	6.32	3.43	128	70	38
Do.....	Not inoculated..	Tops.....	.86	.40	.39
		Roots.....	.13	.14	.11
		Whole plant.....	.99	.54	.50	11	6	5
Alfalfa.....	Inoculated.....	Tops.....	8.25	3.34	3.27
		Roots.....	2.73	2.03	1.10
		Whole plant.....	10.98	5.37	4.37	122	60	49
Do.....	Not inoculated..	Tops.....	.99	.67	.56
		Roots.....	.31	.36	.20
		Whole plant.....	1.30	1.03	.78	14	11	9

Results of lucern tests, season 1914-15, A. E. V. RICHARDSON (*Jour. Dept. Agr. Victoria, 13 (1915), No. 7, pp. 417-436, pl. 1, figs. 10*).—The results of tests in both pot and field experiments as carried on at Werribee are given as follows:

"A lucern crop transpired approximately 681 tons of water to produce 1 ton of dry matter at Werribee for the season 1914-15. By giving a lucern crop as much water as it would use up during the season 1914-15 an equivalent of 8 tons of 16½ cwt. of dry lucern was produced per acre. To produce this quantity, however, no less than 72 acre-inches of water were required, of which 61 acre-inches had to pass through the crop, and 11 acre-inches were dissipated from the soil by evaporation. In field tests the water requirements of lucern were even greater, on account of the impossibility of obtaining a perfect mulch and thus keeping down the loss by evaporation from the soil. On a block of 15 acres, sown in October, 1912, 12.3 tons of commercial hay, containing 10.45 tons of dry matter, were produced in 2½ years. During this period 9.1 acre-feet of water were supplied as rain and irrigation water. Consequently, under field conditions, for every ton of dry hay produced 10½ in. of water were required, 3½ in. of which was lost from the soil by evaporation and 7 in. by transpiration. An acre of lucern in full growth will use up considerably more water

than would be lost by evaporation from a free water surface of equal area. The presence of a sufficiency of soluble phosphates helps to reduce the transpiration ratio, and this makes the crop more economical of water.

"A 15-acre block of lucern yielded 6.5 tons of commercial hay during the second season of growth, and 4.3 tons during the third season, though receiving only three irrigations during the past season. Tamworth lucern has given the best average yield during the past two years, averaging 22½ cwt. per acre for ten cuts. The heaviest seedings of lucern gave the best returns, but there appears to be no material benefit in sowing more than 18 lbs. of seed per acre. Sixteen lbs. is the seeding adopted at Werribee.

"The application of artificial fertilizers gave decided and profitable increases over the unmanured plats. Nitrogenous manures, though not generally used to fertilize leguminous crops, gave the most marked crop increases. Superphosphate proved to be the most efficient of the artificial phosphates. An application of 2 cwt. at seeding, costing 9s., gave an increase of a ton of lucern hay to the acre in the second season of growth, and this in spite of the dryness of the season. Lime has given an increase in crop yields, but the increase was barely sufficient to cover the cost of the application. Heavier dressings than 20 cwt. appear to depress the yield. The effect of these manures will probably be felt next season. Lime has given greater crop increases than an equivalent value of ground limestone, though the effect of the latter manure may be expected to persist longer. In view of the heavy demands made on the mineral constituents of the soil by good lucern crops, top-dressings, applied every winter, of phosphates at the rate of 1½ to 2 cwt. per acre are recommended. On soils similar to Werribee dressings of lime or ground limestone applied every two years at the rate of 10 to 12 cwt. lime and 20 to 25 cwt. ground limestone are likely to prove profitable."

Alfalfa, G. W. CARVER (*Alabama Tuskegee Sta. Bul. 29 (1915), pp. 1-7*).—This bulletin notes the great value of alfalfa as a hay and forage crop as indicated by tests from 1912 to 1915, and gives directions for its production.

Suggestions to alfalfa growers, A. ATKINSON and M. L. WILSON (*Montana Sta. Circ. 49 (1915), pp. 9-42, figs. 31*).—In this circular are discussed the types of alfalfa, methods of production of hay and seed under irrigated and dry-land conditions, and the value of alfalfa as a pasture crop.

Studies on bean breeding.—I, Standard types of yellow eye beans, R. PEARL and F. M. SURFACE (*Maine Sta. Bul. 239 (1915), pp. 161-176, pls. 6*).—It is here stated that observations have shown that the bean, usually a self-fertilized plant, may be cross-pollinated by the action of the large bumblebee, so that for breeding purposes it has been found necessary to erect bean cages inclosed with screen wire. The commercial importance of the Maine bean crop and of the two types of yellow eye beans are discussed. Standards of types, including the characters of sizes and shape, ground color, and eye pattern and color, are suggested for the Improved Yellow Eye and the Old Fashioned Yellow Eye, followed by comments of leading Boston dealers.

Seed values of maize kernels, butts, middles, and tips, MARY G. LACY (*Jour. Amer. Soc. Agron., 7 (1915), No. 4, pp. 159-171*).—This article reviews the work of experimenters along this line with a view to determining how far the apparently contradictory results of different experiments could be reconciled by taking into account the fact that the silks of the kernels from the tip end of the ear are the last to appear, and hence are more likely to escape self-fertilization than other kernels.

The experiments from which these data are compiled cover a period of 45 years, and show that "the average yield of seed from the butt is 103 per cent of that

from the middle seed and the yield of seed from the tips is 105 per cent of that from seed from the middle of the ear. In the case of the tips this is 5 times the probable error for the series, and in the case of the butts, $3\frac{1}{2}$ times. These percentages, though small, must be considered significant in a table of 81 instances. . . . In 4 out of the 81 cases reported we may be sure that the yield has been increased by the use of tip seed, and in the other cases there is no evidence that the use of top seed has decreased the yield. In four cases the increased yield from butt seed is more than four times the probable error.

"The conclusion of the matter seems to be that the tips and butts are certainly not inferior for seed purposes, and there seems little justification for the practice, prevalent in some sections, of discarding them for seed."

A bibliography of 25 titles is appended.

Flax for seed and oil.—Harvesting and storing the crop for seed and oil purposes, H. L. BOLLEY (*North Dakota Sta. Circ. 7 (1915), pp. 4*).—Practical suggestions for the harvesting and storing of flax for seed and oil purposes are given.

Flax crop conditions for 1915 (*Montana Sta. Circ. 48 (1915), pp. 5-8*).—This circular discusses the methods of production and prices obtained for flax with reference to Montana conditions.

The potato crop in Montana, O. B. WHIPPLE (*Montana Sta. Circ. 46 (1915), pp. 141-165, figs. 11*).—In this circular the author discusses methods of production with special reference to the improvement of the potato crop and the growing of potatoes for seed purposes, and includes irrigation and marketing. Descriptions are given of the most important types of potatoes.

Potato spraying and dusting in New Jersey, U. S. A., A. E. CAMERON (*Bul. Ent. Research, 6 (1915), No. 1, pp. 1-21, pls. 3, figs. 2*).—A report of work already noted from another source (E. S. R., 33, p. 336).

Experiments in covering cane by plow and by spade, A. H. ROSENFELD (*Internat. Sugar Jour., 17 (1915), No. 200, p. 364*).—In tests conducted at the Tucumán Experiment Station cane covered in planting with a small share plow produced at the rate of 39,105 kg. per hectare (17.4 tons per acre) as compared with 35,254 kg. for that covered with a spade.

Possibilities of the sweet potato in Macon County, Alabama, G. W. CARVER (*Alabama Tuskegee Sta. Bul. 30 (1915), pp. 22, figs. 8*).—A revised and slightly enlarged reprint of Bulletin 17 already noted (E. S. R., 22, p. 729).

Notes on the germination of tobacco seed, II, T. H. GOODSPEED (*Univ. Cal. Pub., Bot., 5 (1915), No. 7, pp. 233-248*).—This reports the continuation of work previously noted (E. S. R., 29, p. 739), and presents further evidence regarding the relation between the age of the seed of certain pure-line cultures and of the seed of hybrids made between them, and the viability of this seed.

The data "concerning the germination of hybrid *v.* parental seed leave no doubt that different plants of F_1 , F_2 , and F_3 produce seed the germination of which is significantly differentiated as to the total amount of the seed that will germinate, or as to the length of time during which germination takes place, or as to the period, during the extent of the test, within which the maximum amount of germination occurs. Further, there is evidence that among the seeds of a single F_2 or F_3 plant a portion have a characteristic period during which they germinate, which is distinct from the period characteristic of another group of the same seed. . . . Finally, the F_1 seed from reciprocal crosses has been shown to differ with reference to its germination. In this connection, either the amount of total germination, or the extent of the germinating period, or the days of maximum germination peculiar to one parent have been shown also to be characteristic of the cross-pollinated seed which it bore."

The chemical composition of the tobacco plant, E. PANNAIN (*Staz. Sper. Agr. Ital.*, 48 (1915), No. 1, pp. 18-43, figs. 4).—Previously noted from another source (E. S. R., 33, p. 436).

A study of Colorado wheat, W. P. HEADDEN (*Colorado Sta. Bul.* 208 (1915), pp. 3-48).—This bulletin gives results of a study made during 1913 of some factors that may determine the quality of Colorado wheat, which is generally assumed to be inferior to the best bread-making wheat grown in other States.

Wheat was grown on plats that received varying quantities of nitrogen, phosphoric acid, and potash. From the chemical analyses of the soils at various depths before and after fertilization, the analyses of different parts of the wheat plants at several stages of growth, and a study of the bacterial content of the soil, the author is led to believe that there exists a definite relation between the available supply of nitrogen, phosphorus, potash, and moisture in the soil and the quality, or nitrogen content, of the wheat produced thereon. The application of sodium nitrate increased the total amount of ash. It depressed the amount of silica and increased the amounts of potash and calcium, while it did not seem to affect that of phosphorus. The application of phosphorus and potash to the soil seemed uniformly to lower the amount of phosphorus in the plant. The amount of potash in the plant did not seem to have been influenced by the application of either phosphorus or potash. The application of nitrogen to the soil increased the nitrogen in the plant quite materially over that present in the plants grown on the check plats. This was true for each of the different applications made.

Tabulated data show the chemical analyses of soil and subsoil used in these experiments; the variation of total nitrogen, nitric nitrogen, phosphoric acid, and potash in consecutive areas; the percentage of moisture, total nitrogen, and bacterial count of soils differently treated; the effect of varying amounts of nitrogen, phosphoric acid, and potash on (1) the ratio of stems, leaves, and heads for Red Fife varieties of wheat, (2) the amount of dry matter in several varieties of wheat, (3) the total nitrogen, proteid nitrogen, ammoniac nitrogen, and amid nitrogen in wheat plants at different stages of development, (4) the moisture and soluble and insoluble ash in air-dried wheat plants and in various parts of the plants, and (5) the amount of silicon in the different parts of the wheat straw; and the mineral constituents of air-dried wheat straw.

HORTICULTURE.

[Horticultural investigations in Alaska], C. C. GEORGESON (*Alaska Stas. Rpt.* 1914, pp. 11-26, pls. 2).—The investigations of the year were confined principally to the Sitka Station and consisted principally of breeding and cultural experiments with orchard fruits and variety tests with vegetables.

The work of hybridizing strawberries (E. S. R., 32, p. 45) has been continued with success. Many crosses have been made between these hybrids, the best of which are being selected for further study. Notes are given on breeding work now under way with currants, gooseberries, raspberries, blueberries, and cranberries.

Of 40 varieties of apples planted in the station's test orchard some years ago, those which are now left that give any promises of usefulness are the Yellow Transparent, Raspberry, Hyslop, Sylvan Sweet, Whitney, and an English variety, Keswick Codlin. The Yellow Transparent and Raspberry produced fruit last season. The apples were undersized for these varieties but were of very good flavor. The cherry trees at the station continue to make moderate growth and bloom profusely every spring. For some reason, however, possibly

lack of insects to aid in fertilization, 90 per cent of the blossoms drop off without setting fruit. Many supposedly hardy varieties of plums have been grown during the past few years but none of them has produced a bloom.

The usual variety tests with vegetables are reported. A list is given of the shrubs and vines that have proved to be adapted to southeastern Alaska conditions. A list supplementary to that in the 1911 report (E. S. R., 28, p. 436) is also given of hardy perennials, together with annuals or perennials that blossom the first year from seed which were found to do reasonably well last year.

Biennial report State Horticultural Commission of the State of Utah from December 1, 1912, to November 30, 1914 (*Bien Rpt. State Hort. Com. Utah, 1912-1914*, pp. 68).—This report contains a statistical account of the nursery and fruit industry in Utah for 1913 and 1914, together with an account of nursery inspection and quarantine work, including a brief statement of quarantine measures in adjacent States. In addition to statistics on fruit trees planted in 1913 and 1914, data are given of an orchard survey including some 727 blocks of fruit on 357 farms. The various fruits are classified, both with reference to age and acreage and conditions with reference to spraying, cultivation, and pruning. A report is also included relative to the possibilities for fruit product factories in Utah, together with a paper on diversified fruit growing by W. W. Knudson, in which the author gives an account of the management of a farm on which are grown small fruits, cherries, peaches, plums, and vegetables. The data given include the varieties of fruit grown, time of harvest, receipts, and expenses for the three years, 1912-1914. The report concludes with a list of nursery licenses and a financial statement for the biennial period.

The determination of humidity in the greenhouse, M. A. BLAKE (*New Jersey Stas. Circ. 47*, pp. 3-7, fig. 1).—This circular contains directions and tables for the determination of humidity by means of a sling psychrometer.

The origin and history of some of our more common garden vegetables, O. E. WHITE (*Brooklyn Bot. Gard. Leaflets, 3. ser., No. 6 (1915)*, pp. 7, pls. 3).—This comprises brief notes, together with a list showing the supposed origin of most of our common vegetables and the certain or probable date of earliest cultivation.

Morphological and biological researches on the cultivated radishes, YVONNE TROUARD RIOLLE (*Ann. Sci. Agron., 4. ser., 3 (1914)*, No. 7-12, pp. 346-550, figs. 135).—The first part of the work here reported includes a study of differences in color, as measured by the action of acids and bases on the anthocyanin solutions of radishes and by the spectroscopic absorptions of the anthocyanin solutions treated with acids and bases; a study of difference in form of cultivated radishes; a quantitative and qualitative study of carbohydrates in selected types among all the known European, Chinese, and Japanese radishes; a morphological and botanical study of cultivated radishes, including the roots, foliage, flowers, and fruit; and a comparative study of the wild species of *Raphanus*, with special reference to determining the origin of cultivated radishes. In part two of this work are grouped a number of biological investigations, including experiments in the amelioration of forms of the wild radish *Raphanus raphanistrum* into forms of the cultivated radish *R. sativus*; a study of the natural hybrids between the two species; hybridization experiments between different genera of crucifers, different species of *Raphanus*, and crossing experiments between different varieties of *R. sativus*; and a study of the degeneration among cultivated radishes.

Attempts to transform the wild radish *R. raphanistrum* into the cultivated form through cultivation and selection were unsuccessful, although hybrid forms

were secured between the species and were also found to occur naturally. Attempts to cross the wild radish with *Isatis*, *Brassica*, and *Sinapis* were also unsuccessful. From the results of her experiments as a whole the author concludes that the cultivated radish has a dual origin. The Japanese radish (*Daikon*) is descended from *R. sativus raphanistroides*, a native of China and Japan. The European and Chinese radish appears to be derived from another wild type, native to central Asia, and rare or extinct at the present time. The greater number of cultivated radishes are descended from the latter type.

The origin of the radish (*Gard. Chron.*, 3. ser., 57 (1915), No. 1483, p. 296).—An abstract of the above-noted work.

Tomato culture in Montana, L. G. SCHERMERHORN (*Montana Sta. Circ. 44* (1915), pp. 111-119, figs. 5).—A popular treatise on tomato culture discussing location and soils, varieties, planting and transplanting, setting in the field, irrigation and cultivation, pruning and staking, and ripening tomatoes after frost.

Fungicides, insecticides, and spraying calendar (*Fla. Quart. Bul. Agr. Dept.*, 25 (1915), No. 2, pp. 179-194).—This comprises directions for the preparation of fungicides and insecticides, including a spray calendar for both fruits and vegetables.

Bordeaux mixture, M. T. COOK (*New Jersey Stas. Circ. 48*, pp. 3-7).—This circular discusses the preparation of Bordeaux mixture, its use for controlling diseases of various fruits and vegetables, and spraying machinery.

An American fruit farm, its selection and management for profit and for pleasure, F. N. THORPE (*New York: G. P. Putnam's Sons, 1915*, pp. XII+348, pls. 21).—A popular account of fruit farming based primarily on the record of a fruit farm on the southern shore of Lake Erie. The subject matter is treated under the following general headings: Time and the tree, selecting the fruit farm, the planting of the fruit farm, getting along with help, the cultivation of the fruit farm, feeding the land, the fruit farm and the young folks, ten thousand a year, birds and the fruit farm, and the fruit farm and old age.

Systematic cooperation in Nova Scotia, A. E. ADAMS (*Proc. Conf. Fruit Growers Canada, 4* (1914), pp. 43-54).—In this article the author gives a brief history of the development of fruit cooperative companies in the Annapolis valley, with special attention to errors and necessary improvements.

The blooming season of hardy fruits, U. P. HEDRICK (*New York State Sta. Bul. 407* (1915), pp. 367-391).—Continuing previous work (*E. S. R.*, 20, p. 41) the present bulletin, which has been prepared from data secured at the station by various members of the horticultural department, assigns a blooming season for all of the varieties of fruits commonly cultivated in New York. The observations for most of the orchard fruits covered a period of five years, and for grapes and small fruits a period of three years, the blooming seasons given being based upon the opening of the flowers. The varieties are classed as very early, early, midseason, late, and very late.

Ripening dates and length of season for hardy fruits, U. P. HEDRICK (*New York State Sta. Bul. 408* (1915), pp. 393-418).—This bulletin contains the ripening dates and length of season for the same varieties of fruits for which the blooming time is given in the above-noted bulletin.

Dwarf apples, U. P. HEDRICK (*New York State Sta. Bul. 406* (1915), pp. 341-368, pls. 7).—This bulletin comprises a final report of a comparative test of dwarf and standard apples which has been conducted at the station for a period of ten years. French Crab stocks were used for the standard trees and Doucin and French Paradise stock for the dwarf trees. The sites for the tests were selected, with reference to climate and soil, in three widely separated parts of

the States. The general plan of the test was to grow a permanent orchard of standard trees with fillers on Doucin stock and between these trees on Paradise stock. The orchards were set with 27 varieties represented by 1,193 trees.

The results of the investigations show that the union between stock and scion is poorer with Doucin and French Paradise stocks than with the French Crab. Unions were better on Doucin stock than on French Paradise. French Crab was the hardiest stock and French Paradise the least hardy stock. The greatest weakness of the dwarfing stock for New York is the surface rooting habit, in which character the two stocks can not be distinguished. The evil results following surface rooting are winterkilling, uprooting the trees by wind, suckering, and injury in cultivation. Dwarf trees suckered much more than the standard trees. The trees on the three stocks attained the size commonly ascribed to them, those on French Crab being full-sized, those on Doucin medium-sized, and those on French Paradise true dwarfs. Trees on French Paradise came into bearing soonest, Doucin next, and French Crab last. There were no marked differences in size, color, and quality of the apples on the three stocks.

The test has not been such that safe conclusions can be drawn as to which stock makes the most productive orchard. The varieties have not done equally well in the three orchards, and none of the trees are yet near their maximum usefulness. All things considered, however, the most satisfactory varieties on dwarfs have been McIntosh, Wealthy, and Lady. Jonathan, Esopus, Grimes, Alexander, Wagener, Boiken, and Bismarck have been very satisfactory, while Baldwin, Rhode Island Greening, Rome, Ben Davis, Northern Spy, and Sutton have not been very satisfactory on dwarfing stocks. Twenty Ounce has been the most satisfactory.

In this 10-year test no satisfactory time nor method could be found to prune dwarf trees which did not promote a weak, sickly growth. This invariably died back the next winter.

The author concludes that the dwarf trees appeal to amateur rather than to professional apple growers, as they take less space, and therefore permit a greater variety in orchard or garden and are handsomer ornamentals.

The apple in Brittany, E. DUPLESSIX (*Trav. Sci. Univ. Rennes, 10 (1911), No. 2, pp. 1-41, 191-232; 11 (1912), No. 2, pp. 13-23, 41-61, 126-167; 12 (1913), No. 2, pp. 1-29*).—A treatise on apple growing in Brittany, including a discussion of varieties, methods of propagation, orchard management, diseases, and insect pests.

Chemical and biological notes on cherry orchard soils, A. HARVEY and C. H. HOOPER (*Gard. Chron., 3. ser., 57 (1915), No. 1484, pp. 308, 309*).—Data secured by the authors relative to the chemical and physical composition of a number of cherry orchard soils indicate that neither the chemical nor mechanical analysis is a good index of the value of the soil for growing cherries. A favorable soil influences the actual growth of the tree but not necessarily its fruiting capacity. The failure of cherry trees to fruit year after year is apparently due to the lack of suitable cross pollination rather than to some fault in the soil. This may be true even when there are several varieties in the orchard, since they may not be good pollenizers for each other.

Blight resistance in pears and pear stocks, F. C. REIMER (*Better Fruit, 9 (1915), No. 12, pp. 5, 6*).—In this paper the author advances the opinion that the ultimate solution of the pear blight will be the growing of resistant varieties. Attention is called to a number of varieties of *Pyrus communis* which, although of poor quality, are blight resistant and superior to the Kieffer as stocks for top-working with our commercial varieties. It is recom-

mended that such blight resistant varieties be grown in the orchard on resistant *sincensis* stocks for a period of two years and then top-worked with commercial varieties.

Peach growing in Virginia, G. C. STARCHER (*Va. Polytech. Inst. Ext. Bul. 1 (1915), pp. 32, figs. 13*).—A popular discussion of some of the more important problems in peach growing with special reference to Virginia conditions. Consideration is given to selecting the location for the commercial peach orchard, soil and site, varieties, planting operations, selection of trees and time to plant, arranging varieties, tillage, pruning, thinning, picking, packing equipment, and insect and disease control.

Inheritance of certain characters of grapes, U. P. HEDRICK and R. D. ANTHONY (*U. S. Dept. Agr., Jour. Agr. Research, 4 (1915), No. 4, pp. 315-330*).—This work discusses certain results of breeding experiments with grapes which were begun at the New York State Experiment Station by E. S. Goff in 1885 and have been continued and increased from year to year by subsequent investigators. The work is now proceeding mainly along two lines: The determination of the breeding potentialities of a considerable number of varieties of grapes, especially with the view of finding unit characters; and a review of all the station's breeding data on this fruit, the necessary crosses being made to throw further light upon doubtful points. Nearly 200 varieties of grapes have been used in the breeding work but much of the value of the early work was lost by growing too few seedlings of each cross. Recently *Vitis vinifera* has been used to a considerable extent in hybridization.

The results as a whole have compelled the belief that improved varieties of grapes will not be produced to any extent until the fundamental laws of heredity are understood. One of the surprises in the study of grape varieties was the failure of many commercial sorts to transmit desirable qualities. Nearly 3,000 selfed, or pure, seedlings have been grown. They are uniformly lacking in vigor.

The work shows that reflexed stamens are correlated with complete or nearly complete self-sterility and upright stamens with self-fertility. Partial or complete self-sterility is probably caused by impotent pollen and depends to some extent upon the condition of the vine and environmental factors. Breeding from varieties with upright stamens decreases but does not eliminate the seedlings with reflexed stamens. Sex inheritance seems to be transmitted as follows: Hermaphrodite female \times hermaphrodite male = all hermaphrodites. Hermaphrodite female \times pure male = $\frac{1}{2}$ hermaphrodites + $\frac{1}{2}$ males.

With reference to skin color, white is a pure color and is recessive to both black and red. No black or red varieties have proved pure for blackness or redness. The colors of pure seedlings of certain varieties show wide variation, even when derived from varieties of similar color.

The most noticeable observation as to quality was the low percentage of seedlings whose quality is good or above good. This is attributed to the leveling influence of the wild ancestors, from which the seedlings are but a step removed. Most grapes of high quality possess some *V. vinifera* blood. This predominance of high quality is probably due to the intense selection to which the species has been subjected for centuries. Pure seedlings in this work have been lower in quality than crossed seedlings.

Relative to the inheritance of size of berry, there was no indication of dominance of any size, though there is a tendency for a variety to produce seedlings approaching its own size. It is suggested that the oval form of many *V. vinifera* hybrids is an intermediate between round and a more pronounced oval. Oblate may be a pure form recessive to round. The season of ripening of the parent influences to a considerable extent the season of the offspring.

A vineyard of 1,500 seedlings bred from 1898 to 1903 has by a process of vigorous selection decreased to less than 75 vines; but among this number are several that seem very promising. Five of these have been tested, named, and placed in the hands of nurserymen.

A short bibliography of cited literature is appended.

Combination spraying experiment for the control of mildew and leaf-hoppers on grapevines, S. W. FOSTER (*Mo. Bul. Com. Hort. Cal.*, 4 (1915), No. 5-6, pp. 250-253).—Experiments conducted in 1914 by the author in cooperation with R. M. Roberts and F. P. Roullard indicate that in vineyards where mildew does not cause any injury until after the grapes are through blooming both vine hoppers and mildew can be effectively controlled by one application of the following formula: Atomic sulphur, 24 lbs., blackleaf 40 or sulphate of nicotin 1 pint, and water to make 200 gal. On varieties where the undersurfaces of the leaves are covered with excessive hairy pubescence or when many of the hoppers are more than half grown it is of advantage to add from 0.5 to 1 gal. of liquid whale-oil soap to each 200 gal. of spray. In those vineyards where mildew begins development early in the season the vines should be sprayed once before blooming for mildew control, although no good can be accomplished in vine-hopper control by spraying at this time.

Factors governing the successful shipment of red raspberries from the Puyallup Valley, H. J. RAMSEY ET AL. (*U. S. Dept. Agr. Bul.* 274 (1915), pp. 37, figs. 26).—This bulletin is based upon handling, storage, shipping, and precooling experiments with red raspberries conducted by the Office of Horticultural and Pomological Investigations during the seasons of 1911, 1912, and 1913. The subject matter is presented under the general headings of the berry industry of the Puyallup Valley, methods of growing red raspberries, handling and shipping red raspberries, causes of decay of fruit in transit, frequency of picking, relation of rainfall to handling, relation of methods of growing to keeping quality, the labor problem, handling—an economic problem; careful handling experiments, effect of delay in cooling or keeping quality, precooling experiments, decay in top and bottom crates, temperature conditions in an iced refrigerator car, and the application of precooling.

The results of these investigations demonstrate that care exercised in handling and the promptness with which the fruit is cooled are among the most important factors in determining the distance red raspberries can be successfully shipped. A number of recommendations are made with special reference to facilitating and improving methods of handling, shipping, and precooling.

Ettersburg strawberries, R. E. CLAUSEN (*Jour. Heredity*, 6 (1915), No. 7, pp. 324-331, figs. 3).—A popular account is given of the strawberry breeding work of A. F. Etter, of Briceland, Cal.

The author concludes that the most important result of this work is the demonstration of the fact that further hybridization of the common garden varieties of the strawberry, supposedly largely *Fragaria chiloensis* derivatives, with wild forms of that species results in a notable increase in vigor and in the production of new varieties superior in every respect to the ones commonly cultivated.

The citrus grove, its location and cultivation, P. H. ROLFS (*Fla. Quart. Bul. Agr. Dept.*, 25 (1915), No. 2, pp. 135-154).—An account of citrus culture in Florida with special reference to the selection of location and site, preparation of land, cultural treatment, and building up a neglected grove.

The fertilizer requirements of citrus trees, H. J. WEBBER (*Mo. Bul. Com. Hort. Cal.*, 4 (1915), No. 5-6, pp. 225-230; *Proc. Fruit Growers' Conv. Cal.*, 45 (1914), pp. 101-107).—The results of the first five fruiting years are given

of fertilizer experiments with oranges and lemons which were started by the California Citrus Station in 1907.

The results thus far indicate very strongly the importance of nitrogen fertilization and the desirability of using nitrogen from organic sources. Potash appears to be unnecessary for the fertilization of young groves, and it is doubtful whether phosphoric acid is required in such large quantities as ordinarily are used. In lieu of further experimental results the author concludes that in general one of the factors of fundamental importance in citrus groves is to increase the amount of organic matter in the soil. This can probably best be done by the regular use of a winter cover crop such as Melilotus or purple vetch and the application of manure, alfalfa hay, bean straw, and similar materials as fertilizers.

Suggestions on coffee planting for Porto Rico, T. B. McCLELLAND (*Porto Rico Sta. Circ. 15 (1915), Spanish ed., pp. 23 pls. 4, fig. 1*).—A Spanish edition of the circular previously noted (E. S. R., 28, p. 237).

Coffee: Its cultivation and manuring in South India, R. D. ANSTEAD (*Dept. Agr. Mysore, Gen. Ser. Bul. 6 (1915), pp. 48, fig. 1*).—A practical treatise on coffee culture, the introductory chapter of which discusses the botany of the coffee plant. The succeeding chapters deal with planting the estate, selection of seed, nurseries, planting out, supplies, cultivation and preparation of the soil, renovation of old coffee, draining, shade, regulation of shade, pruning, weeding, mulching, humus, manurial value of mulch, manuring of coffee, valuation of manures, mixing of fertilizers, the use of lime, green manuring, and handling the crop.

Notes on the spraying of tea, E. A. ANDREWS and A. C. TUNSTALL (*Indian Tea Assoc. [Pamphlet] 1 (1915), pp. IV+75, pls. 9*).—This work discusses the more important insect pests and fungus diseases of the tea plant and gives directions for the preparation and use of sprays for their control.

Bearing dates for grafted shagbark.—A new method for grafting nut trees, R. T. MORRIS (*Amer. Nut Jour., 2 (1915), No. 6, p. 87*).—After briefly noting that Taylor grafts upon a top-worked shagbark stock came into flower the fourth year, the author describes a new method of grafting herbaceous grafts of shagbark hickory and English walnuts which has been used the present spring.

The method consists in mixing one part of commercial grape juice with three parts of water and dipping the grafting knife into this solution just in advance of cutting the scions or stock. The solution bathes the cut surface and not only prevents instantaneous drying of the surface, but also inhibits the enzymic action which otherwise takes place very rapidly with the effect of discoloring the cut surfaces. The grafts were all made according to the side-cleft method. Although no conclusive results have been secured as yet, scions not more than 2 in. in length gave so much promise of living two weeks after the grafting period that the method is described with a view to encouraging further experiments along this line.

The industrial cultivation of aromatic plants for essences and medicines, C. CRAVERI (*Coltivazione Industriale delle Piante Aromatiche da Essenze e Medicinali. Milan: Ulrico Hoepli, 1914, pp. XIX+307, pls. 24, figs. 71*).—A practical manual on the culture of essential and medicinal plants.

Part 1 contains general instructions relative to the selection and preparation of soils, nursery and seed-bed practices, methods of propagation, cultural operations, harvesting, marketing, drying, etc. Part 2 takes up specifically the botanical characteristics, cultivation, method of harvesting, and preparation and uses of various plants. Part 3 treats of diseases and insect pests and

their control, and gives selections of plants suitable for growing in various situations and types of soil. Part 4 comprises a botanical glossary. The text is accompanied by a series of colored plates illustrating the more important plants discussed.

Crossing experiments with canna varieties, J. A. HONING (*Rec. Trav. Bot. Néerland.*, 12 (1915), No. 1-2, pp. 1-26, figs. 2).—Data secured from a study of character inheritance in the joint progeny of two varieties of cannas are here presented in tabular form and discussed. The results secured from a study of the first two generations indicate that for *Canna indica* character transmission occurs not only according to Mendel's law, but there are three completely independent lines of inheritance.

Heredity of color in *Phlox drummondii*, A. W. GILBERT (*U. S. Dept. Agr., Jour. Agr. Research*, 4 (1915), No. 4, pp. 293-301, pls. 3).—A Mendelian study of color transmission in *P. drummondii*, conducted at the New York Cornell Station, including a review of our knowledge relative to the nature of color in plants. Commercial seed was purchased and the different varieties grown and self-fertilized for three years so as to be sure of pure types. The varieties used in these experiments were found to breed true for three years and are assumed to be pure. The parents were self-fertilized each year and grown alongside of the F_1 and F_2 hybrids. The flowers of a number of the seed parents and hybrids are illustrated in color.

The unit characters found in the four varieties of *P. drummondii* that were used in these experiments include (1) a dark eye factor producing a dense coloration at the center of the flower. This was dominant over its absence, the white eye, which was exhibited in more or less of a definite pattern. (2) A blue factor. (3) A red factor. (4) An intensifying factor which determines the degree of pigmentation of the reds. (5) A yellow factor which acts only in the presence of the eye factor. The reds and blues are cell-sap colors, and the yellow is due to the presence of yellow chromoplasts.

The National Rose Society's rose annual for 1915, edited by H. R. DARLINGTON (*London: National Rose Society, 1915, pp. 164, pls. 22*).—This consists of several articles on various phases of rose culture, including also descriptions of new varieties of 1914.

Italian gardens of the Renaissance, JULIA CARTWRIGHT (*London: Smith, Elder & Co., 1914, XII+298, pls. 16*).—This work comprises sketches of a number of Italian gardens and their makers.

FORESTRY.

[Forestry report for 1914] (*Rap. Dept. Suisse Int., 1914, pp. 1-9*).—A report on forest legislation, management, felling, and planting operations for the year 1914.

Annual progress report on forest administration in the Presidency of Bengal for the year 1913-14, C. E. MURIEL (*Ann. Rpt. Forest Admin. Bengal, 1913-14, pp. II+49+5*).—A progress report on the constitution, management, and exploitation of the state forests of Bengal, including a financial statement for the year 1913-14. All important data relative to alterations in forest areas, forest surveys, working plans, forest protection, revenues, expenditures, etc., are appended in tabular form.

Annual progress report of the forest administration in Coorg for the year 1913-14, H. TREMAN (*Rpt. Forest Admin. Coorg, 1913-14, pp. 4+11+13*).—A progress report on the administration and management of the state forests in Coorg, including a financial statement for the year 1913-14, with a review of the work by the chief commissioner. All important data relative to alterations

in forest areas, forest surveys, working plans, forest protection, miscellaneous work, yields in major and minor forest products, revenues, expenditures, etc., are appended in tabular form.

The State and forestry in Ireland, A. C. FORBES (*Quart. Jour. Forestry*, 9 (1915), No. 3, pp. 214-225).—A short review of the history of forestry in Ireland with special reference to the development of state forestry in recent years.

The Tintern crown forests, W. SCHLICH (*Quart. Jour. Forestry*, 9 (1915), No. 3, pp. 194-204, pl. 1).—A descriptive account of these forests and the system of management applied to them during the last fourteen years.

Some developments in reforestation on the National Forests, C. R. TILLOTSON (*Forest Club Ann. [Univ. Nebr.]*, 6 (1915), pp. 103-109).—An account of the more important developments in reforestation work, with special reference to nursery practice, sowing, and planting.

The quadrat method as applied to investigations in forestry, A. W. SAMPSON (*Forest Club Ann. [Univ. Nebr.]*, 6 (1915), pp. 11-31, pl. 1, figs. 6).—In this article the author explains the use of the quadrat method of study in forestry and gives some results obtained through the application of this method in growth and management studies undertaken at the Utah Forest Experiment Station on the Manti National Forest.

On the harmful effects of the growth of certain grasses and weeds around the roots of young forest trees, S. F. ARMSTRONG and E. R. PRATT (*Quart. Jour. Forestry*, 9 (1915), No. 3, pp. 225-230, pl. 1).—In the authors' experiments, which are being conducted at Ryston, a large number of grasses were grown at the base of young forest trees. The results for the 3-year period, 1912-1914, are in accord with those reported by the Duke of Bedford and S. U. Pickering for fruit trees (E. S. R., 26, p. 639). They also indicate that the harmful effects of grass are the result of some soluble toxic substance produced by growing plants. The plats have been retained for further observation.

Some methods in the germination tests of coniferous tree seeds, J. S. BOYCE (*Forest Club Ann. [Univ. Nebr.]*, 6 (1915), pp. 71-88).—A résumé of the literature on the subject, including also a description of methods of making germination tests and results secured by the author.

Variation in the size of ray pits of conifers, F. B. H. BROWN (*Ohio Nat.*, 15 (1915), No. 8, pp. 542-550, figs. 6).—A comparative study of variations in ray characters in *Larix* and *Picea*, including charts and tabular data showing variations in size and number of ray pits through one annual ring in *Larix laricina*, *L. occidentalis*, *Picea sitchensis*, and *C. canadensis*.

A new industry in Middle Park: The collection of lodgepole pine cones, A. T. URSON (*Forest Club Ann. [Univ. Nebr.]*, 6 (1915), pp. 32-40).—A descriptive account of the methods of collecting lodgepole pine cones in Colorado and the extraction of seed by the Forest Service of the U. S. Department of Agriculture. See also a previous note by Farquhar (E. S. R., 29, p. 444).

The older forest plantations in Massachusetts.—Conifers, J. R. SIMMONS (*Boston: State*, 1915, pp. 38, pls. 11).—The author here presents data secured in 1914 on a number of forest plantings of coniferous trees which have reached an age when value can be measured in terms of lumber. The plantations are considered with reference to their history, objects, and treatment, and data are also given showing growth measurements, the number of trees, and estimated amount of lumber in sample plats.

Structure of the wood of Himalayan junipers, W. RUSHTON and W. PADBINGTON (*Jour. Linn. Soc. [London], Bot.*, 43 (1915), No. 288, pp. 1-13, pl. 1).—A macroscopic and microscopic study of the wood structure of four species of

Himalayan junipers is reported. The chief points of interest brought out are the shortness of the tracheids of all species, the resinous nature of the medullary rays, the distribution of the resin cells in the annual ring, and the nature of the rims above and below the pit areas, these being shown to agree with those of the East Indian pines in being of the nature of pectin and not cellulose.

Relationships of the white oaks of eastern North America, with an introductory sketch of their phylogenetic history, MARGARET V. COBB (*Proc. Amer. Phil. Soc.*, 54 (1915), No. 217, pp. 165-175, pls. 3, fig. 1).—This article contains a reconstruction of the history of the Fagaceæ and of *Quercus*, together with a key showing the relationships of the white oaks of eastern North America. A bibliography of related literature is included.

Discussion on the eucalypts and their products, H. G. SMITH (*Rpt. Austral. Assoc. Adv. Sci.*, 14 (1913), pp. 116-125).—A discussion of the essential oil products of the eucalypts with reference to their tanning capabilities and other avenues of possible utilization.

Culture of *Manihot glaziovii* at the State Agricultural Station at Bokala, Middle Kongo, JANSSENS (*Bul. Agr. Congo Belge*, 5 (1914), No. 3, pp. 416-456, figs. 17).—An account of cultural, tapping, and coagulation work with *M. glaziovii* rubber at the station, including estimates relative to the cost of establishing a rubber plantation and the probable returns, and a discussion of the diseases and other enemies of *Manihot*.

The treatment to which the Para rubber trees of the Botanic Gardens, Singapore, have been subjected (*Gard. Bul. Straits Settlements*, 1 (1915), No. 8, pp. 247-295, pls. 4).—An account of the early distribution of Para rubber plants in the Tropics and their introduction and culture in Singapore, with special reference to tapping experiments. Data are given on various tapping experiments conducted in the Botanic Gardens, together with tabular data on seed-bearing trees in the garden and the seed crop over a long series of years.

Rattan supply of the Philippines, J. R. ARNOLD (*U. S. Dept. Com., Bur. Foreign and Dom. Com., Spec. Agents Ser.*, No. 95 (1915), pp. 40).—A statistical report on the supply of Philippine rattan and its suitability as to quality, cost of exploitation, etc., for placing in quantities on the export market. The data were collected principally by the Philippine Bureau of Forestry.

Wood-using industries of the Prairie Provinces, R. G. LEWIS and W. G. H. BOYCE (*Dept. Int. Canada, Forestry Branch Bul.* 50 (1915), pp. 75, figs. 17).—This report contains an account of the quantity, value, and source of supply of the different kinds of wood used by the industries of the Provinces of Manitoba, Saskatchewan, and Alberta. It includes detailed descriptions of the different classes of industries and of the properties of the different woods used in these industries. A discussion of the possible uses of the native woods of these Provinces and a classified list of the commodities manufactured from different woods are appended.

DISEASES OF PLANTS.

The vegetable parasites of cultivated or useful plants, T. FERRARIS (*I Parassiti Vegetali delle Piante Coltivate od Utili. Milan: Ulrico Hoepli, 1915, pp. XII+1033, app. pp. XIX, pl. 1, figs. 185*).—This edition differs from the first (*E. S. R.*, 29, p. 644) chiefly in having an appendix dealing briefly with some recent articles on parasitic bacteria and fungi.

Fungus diseases, J. P. ANDERSON (*Alaska Stas. Rpt. 1914, pp. 26, 27*).—Notes are given on a number of diseases of economic crops observed during the year. The author states that the most injury is caused by *Botrytis cinerea*

which is observed to attack at least 25 species of plants, including ornamental plants and small fruits.

In addition, the presence of *Nectria cinnabarina* is reported on currant canes as well as on a number of other woody plants. The gooseberry mildew (*Spharotheca mors-uvæ*) was observed on English gooseberries, and the gooseberry rust (*Æcidium grossulariæ*) was found on gooseberries and currants. The apple scab (*Ventura pomii*) was common on a number of the more susceptible varieties of apples grown in the nursery, and was also found to attack the wild crab apple.

Club root of cabbage and other cruciferous plants is reported as common. In addition, a leaf spot of salmonberry due to *Septoria rubi*, a rust of thimbleberry due to *Phragmidium rubi*, and a pea disease probably caused by *Ascochyta pisi* are also reported as being observed.

Overwintering of parasitic fungi by means of mycelium, O. TREBOUX (*Mycol. Centbl.*, 5 (1914), No. 3, pp. 120-126).—The author reports in detail his observations on *Puccinia dispersa*, *P. glumarum*, *P. obscura*, *P. arcnariæ*, *P. poarum*, *P. agropyrina*, *P. coronata*, *P. carduorum*, *Uredo airæ*, *U. festucæ*, *Thecopsora pirota*, *Erysiphe graminis*, and *Mclampsora lini* on various hosts named in regard to their ability to survive the winter in the dry climate of the steppes, which is thought to be favorable to such overwintering.

A new North American Endophyllum, J. C. ARTHUR and F. D. FROMME (*Bul. Torrey Bot. Club*, 42 (1915), No. 2, pp. 55-61, pl. 1, figs. 2).—This is a detailed account of investigations noted elsewhere (E. S. R., 32, p. 749.)

Rhizostilbella rubra, a by-fruit form of *Ascobolus parasiticus*, and its connection with the Sclerotium disease of certain tropical cultivated plants, P. C. VAN DER WOLK (*Mycol. Centbl.*, 4 (1914), No. 5, pp. 236-241, pl. 1).—The author has studied a fungus found growing on rotting fruits and stalks of *Voandzeia subterranea* and has found that it exists in three forms or stages, which are designated as *A. parasiticus* n. sp., *S. omnivorum* n. sp., and *R. rubra* n. g. and sp.

Abnormal distribution of fruiting bodies in *Ustilago tritici*, E. RIEHM (*Ber. Deut. Bot. Gesell.*, 32 (1914), No. 8, pp. 570-573, pl. 1).—The author has been able to confirm the statement made by Hennings (E. S. R., 6, p. 147) to the effect that *U. tritici* may be found developing its spore masses on the axis of the ear, also inside and outside the blades and sheaths of the upper leaves of wheat as well as in the flowers of this plant.

Cross sections showed the presence of the mycelium in the mesophyll, but not in the vascular bundles. Spore formation occurred between the latter, which accounts for the longitudinal streaking observed. The mycelium was intercellular in a majority of cases.

Mildew of the peach and rose, N. WORONICHIN (*Trudy Bûuro Prikl. Bot. (Bul. Angew. Bot.)*, 7 (1914), No. 7, pp. 441-450).—It is stated that inoculation of the peach with conidia of *Spharotheca pannosa* from the rose gave negative results and that a careful study of the perithecia, asci, and spores showed differences in their dimensions as found on these different hosts. It is thought that the biological and morphological differences noted are sufficient to separate the species into the varieties *S. pannosa rose* and *S. pannosa persica*.

Deformation of oat leaves, ZADE (*Fühling's Landw. Ztg.*, 63 (1914), No. 18, pp. 593-595, fig. 1).—A deformation of the youngest leaf of oats with some dwarfing is discussed as related to growth while enrolled in the bud.

Stagonospora cassavæ n. sp., P. C. VAN DER WOLK (*Mycol. Centbl.*, 5 (1914), No. 5, pp. 225-230, figs. 10).—A severe disease of cassava (*Manihot utilissima*) appeared very suddenly at Buitenzorg early in 1913 and threatened to become

a source of much loss. The causal fungus, *S. cassavae*, is a typical wound parasite, attacking only, so far as yet observed, the cut surface of the slip which is above ground. It is said to be controlled by an early application of tar to such portions.

The description of the fungus shows an instance of spore formation within certain cells or sections of the mycelial threads. Such swollen and spore-bearing portions are regarded as asci, and several forms are noted. Pycnidia and pycnospores are also described.

Two physiological affections of Sea Island cotton in the West Indies, W. NOWELL (*West Indian Bul.*, 14 (1914), No. 4, pp. 304-317, pls. 3).—Descriptions are given of curly leaf and loggerhead of cotton in the West Indies. These are supposedly distinct physiological diseases, having been known in this region since about 1910.

Curly leaf appears to be related in some way with rapid growth, resulting from abundant water supply in still, cloudy weather, shade, and crowding, in connection with certain soil conditions, including depth and easy permeability. Loggerhead disease is very erratic in its occurrence, and its relation to weather conditions is not quite clear.

The incidence of either disease in any year is strictly local, cases of severe damage being rare and of limited extent. Neither disease appears to be increasing or to be connected with any particular kind of seed, and no remedial measures are known or suggested.

A bibliography is given.

Cruciferous club root and gall weevil injury, O. SCHLUMBERGER (*Deut. Landw. Presse*, 41 (1914), No. 83, pp. 910, 911, pl. 1, figs. 3).—This is a discussion of the appearance and effects of slime mold (*Plasmodiophora brassicae*) on crucifers as contrasted with injury due to gall weevils, which somewhat resembles it externally.

Rheosporangium aphanidermatus, a new genus and species of fungus parasitic on sugar beets and radishes, H. A. EDSON (*U. S. Dept. Agr., Jour. Agr. Research*, 4 (1915), No. 4, pp. 279-291, pls. 5).—In a previous publication (E. S. R., 29, p. 646) the author called attention to this disease and later has given a description of its pathogenic properties (E. S. R., 33, p. 246).

The present paper deals with studies on the morphology, cytology, and taxonomy of the organism which has been described as *R. aphanidermatus* n. g., and n. sp.

Apple spraying experiments in 1914, W. J. MORSE and M. SHAPOVALOV (*Maine Sta. Bul.* 240 (1915), pp. 177-196).—In continuation of experiments in apple spraying (E. S. R., 31, p. 151), the authors give an account of the results of their investigations in 1914.

A series of plats embracing 282 Ben Davis apple trees was sprayed with different fungicides to determine their relative efficiency for the control of apple scab, and also for their effect upon the foliage and fruit of the trees. Different plats of trees were sprayed with Bordeaux mixture, lime sulphur, "soluble sulphur," "atomic sulphur," copper lime sulphur, extra fine sulphur, and arsenate of lead, arsenate of lead being added as an insecticide to the different fungicides. Notes were taken of the effect of the various sprays on the foliage and fruit during the summer, and when the fruit was gathered the different lots were examined for the percentage of scabbed and russeted fruit.

Bordeaux mixture showed the greatest efficiency in scab control, but it also resulted in the largest amount of russeted fruit. Different dilutions of lime sulphur proved satisfactory, and as a result of three seasons' work it is concluded that the strength of this solution can be increased about 20 per cent

with comparative safety. "Soluble sulphur," even when reduced to $\frac{3}{4}$ lb. in 50 gal. of water, caused serious defoliation of the trees, and as a result of this and previous experiments it is not considered safe to use. Where "atomic sulphur" was used, scab control was very efficient and the amount of russetting was less than that observed on the unsprayed check plot. The copper lime sulphur did not give any better scab control than ordinary lime sulphur, and the amount of leaf injury and fruit russetting was largely increased by the use of this fungicide. The extra fine sulphur did not give as good results as some of the other mixtures employed, although it had considerable efficiency in scab control. With arsenate of lead as a summer spray for apple trees the scab control on the fruit was very efficient. The experiments show that arsenate of lead has an important effect as a fungicide, although the results were not so favorable as those previously obtained.

In connection with this experiment the effect of omitting the earlier spraying was tested. It was found that if circumstances arise which cause the delay of the earlier application, or cause it to be entirely omitted, this does not necessarily imply failure in scab control if the later applications are made in due time.

Plectodiscella piri, representing a new Ascomycete group, N. N. WORONICHIN (*Trudy Būro Prikl. Bot. (Bul. Angew. Bot.)*, 7 (1914), No. 7, pp. 431-440, pl. 1; *Mycol. Centbl.*, 4 (1914), No. 5, pp. 225-233, pl. 1, figs. 8).—An account is given of the study of a disease of pear and apple leaves in the Caucasus, said to be due to a fungus hitherto unknown. This is described as *P. piri* n. g. and sp., the representative of a new family which is named *Plectodiscellae*.

Silver leaf, T. A. C. SCHOEVEERS (*Tijdschr. Plantenziekten*, 20 (1914), No. 1, pp. 36-41, pl. 1).—Noting studies on the attack of *Stereum purpureum* on stone fruits and other plants, as carried out in 1913 at Wageningen, the author states that the exact nature of the connection between the silvered appearance of the leaves and the presence of the fungus in the wood vessels is still undetermined.

Complete destruction of diseased parts is advised, also treatment of wounds with tar or carbolineum. Earth from near trees suffering from the disease should not be placed near sound ones. Material for grafting should be carefully inspected. Sufficient water supply should be provided, especially for dry weather. Growths liable to harbor the fungus should be removed from the neighborhood of susceptible plants.

Red raspberry injury caused by *Sphærella rubina*, W. G. SACKETT (*Colorado Sta. Bul.* 206 (1915), pp. 26, pl. 1, figs. 15).—The author describes the injury done to raspberries by the fungus *S. rubina*, and gives an account of spraying experiments for its control. These experiments were carried on for two seasons, a 3:2:50 Bordeaux mixture being used, to which 2 lbs. of rosin fish oil soap was added. Three applications were given the canes, only the young canes being sprayed and the old ones being removed and burned as soon as the berries had been gathered.

As a result of spraying, a net gain of \$167.26 per acre was estimated, at a cost of \$10.24 per acre for materials and application.

Notes are also given on the effect of late frost, methods of covering, time of taking up canes, poor cultivation, age of plantations, etc., on raspberry production.

Bordeaux mixture as a citrus spray, G. L. FAWCETT (*Porto Rico Prog.*, 8 (1915), No. 13, pp. 6, 7).—The comparative fungicidal values of fresh Bordeaux mixture, a commercial preparation of the same, and a dry powder of copper sulphate and lime were tested for leaf rot fungus on coffee trees. The freshly

made Bordeaux mixture was fully effective, but the other two were impaired by rain which fell a few hours after their application, adherence thus appearing to be a deciding factor.

The scale-destroying fungi on the interior branches of citrus trees ordinarily remain uninjured in sufficient numbers to control scale insects after spraying, except occasionally in dry weather. An insecticide should follow or precede the Bordeaux mixture on trees which show many scale insects, indicating a deficiency of scale-destroying fungi. It is considered that no ready-made fungicide on the market is superior to freshly made Bordeaux mixture.

Fungi parasitic on the tea plant in northeast India, III, IV, A. C. TUNSTALL (*Indian Tea Assoc., Sci. Dept. Quart. Jour., 1914, Nos. 2, pp. 52-54; 3, pp. 96-98*).—Continuing previous reports (*E. S. R., 32, p. 346*) the author states that *Nectria caneri*, associated with canker of tea bushes, probably attacks its host originally through cavities resulting from improper pruning or injuries by hail, cattle, etc. Spores grown in the laboratory have not given successful inoculations up to the present time. As the fungus travels readily downward it is necessary to cut away all dead twigs and some depth of living wood for a distance below the dead portion, applying Bordeaux mixture freely.

Copper blight (*Laetia theæ*) is contrasted symptomatically with gray blight (*Pestalozzia palmarum*) and with brown blight (*Collectotrichum camelliae*). Copper blight is more noticeable during drought succeeding heavy rains, and so is often attributed to hot sunshine, which may hasten development of the fungus and browning of the leaves. Removal of all affected leaves and application of Bordeaux mixture should immediately follow the appearance of this disease, and a second spraying should follow two weeks later. For cases of general infection a treatment to be used during cold weather is outlined which is claimed to remove copper blight, also minor blights, and to stimulate production by the tea bushes.

Ascochyta clematidina, the cause of stem rot and leaf spot of clematis, W. O. GLOYER (*U. S. Dept. Agr., Jour. Agr. Research, 4 (1915), No. 4, pp. 331-342, pls. 5*).—A stem rot of clematis due to *A. clematidina* is described from the New York State Experiment Station, the disease attacking various species and hybrids and occurring in the field as a stem rot, while in the greenhouse where cuttings are propagated it is present both as a leaf spot and as a stem rot. On *Clematis paniculata* the disease takes both forms. The plants are killed by the growth of the fungus down the petioles into the stems, thus girdling the plant at the node. Overwintering out of doors does not kill the fungus in cultures or on dead vines.

The disease has been successfully produced by inoculating plants with mycelium from pure cultures. Matting of the vines produces a condition which is favorable for the spread of the disease, and ventilation should be secured by supporting the vines or planting them far apart. On hybrid plants the disease can be controlled in the forcing frames or in the greenhouse by the use of sprays, but in the field spraying proved of little benefit. On *C. paniculata* spraying checked the disease, and the removal of diseased leaves and vines before spraying was also found of practical value in controlling the trouble. A mixture of 1 lb. of laundry soap and 6 lbs. of sulphur to 15 gal. of water sprayed on cuttings in the greenhouse or in beds controlled the disease.

A list of cited literature is appended.

Dying out of oaks in Westphalia, BAUMGARTEN (*Ztschr. Forst u. Jagdw., 46 (1914), No. 3, pp. 174-177*).—This is a brief discussion of recent losses from death of forest oaks as related to leaf rollers, mildew, and honey fungus, and of some views regarding the fundamental causes related thereto.

Species of *Loranthus* on rubber trees, F. T. BROOKS (*Agr. Bul. Fed. Malay States*, 3 (1914), No. 1, pp. 7-9).—The presence is reported of *Loranthus* on rubber trees or estates in Negri Sembilan.

Infection of wood by *Coniophora*, *Trametes*, and *Polyporus*, C. WEHMER (*Ber. Deut. Bot. Gesell.*, 32 (1914), No. 8, pp. 566-570).—Discussing briefly the results of investigations previously reported (*E. S. R.*, 32, p. 845) and of others more recently carried out, the author states that infection is assured only when the fungus extends itself from mycelium already growing attached.

Experiments of a preliminary character with *T. radiciperda* (*P. annosus*), *C. cerebella*, *P. vaporarius*, and *P. sulfurcus* on moistened fir wood kept in flasks for eight weeks showed comparatively little development in case of wood sterilized before infection and almost none in case of unsterilized wood, while early and vigorous growth was observed on beer wort. The possible bearings of these facts are discussed.

The chemical action of the dry rot fungus on the substance of wood, C. WEHMER (*Ber. Deut. Bot. Gesell.*, 32 (1914), No. 9, pp. 601-608).—The author has extended his studies on the acidity apparent in connection with dry rot fungi (*E. S. R.*, 32, p. 150). *Coniophora* and *Merulius* were both tested as to their effects on fir wood.

It is stated that wood attacked by these fungi is no more acid than is sound wood. It is held that the reddening of the litmus in this connection is probably not due to the presence of acid substances, but that it is a result of colloidal action resulting from the acidity of the fungi.

The toxicity to fungi of various oils and salts, particularly those used in wood preservation, C. J. HUMPHREY and RUTH M. FLEMING (*U. S. Dept. Agr. Bul.* 227 (1915), pp. 38, pls. 4).—The results are given of tests of 18 wood preservatives against two wood-destroying fungi, *Fomes annosus* and *F. pinicola*.

The method employed was to determine the toxicity of the preservative on the fungus grown in Petri dishes. While some inaccuracies were found in this method, in general it was considered a satisfactory means of determining the toxicity of the different compounds.

In addition to a report on other investigations, the authors give a summary of the results of the various investigators of this subject. It is claimed that the chemical and physical composition of the media supporting the growth of the fungus determines to a large extent its development. Temperature is also an important factor in the growth of fungi, and the growth activities of fungi are believed to bear a close relation to the resistance offered toward toxic agents.

The results of the experiments show wide variation in the amount of the preservatives required per cubic foot of culture medium and also marked differences in their effects on the two species of fungi experimented upon.

A bibliography is appended.

Toxicity of various wood preservatives, C. J. HUMPHREY and RUTH M. FLEMING (*Jour. Indus. and Engin. Chem.*, 6 (1914), No. 2, pp. 128-131; 7 (1915), No. 8, pp. 652-658, figs. 4).—A detailed report of the investigation described in these papers is given above.

***Wallrothiella arceuthobii*, J. R. WEIR (*U. S. Dept. Agr., Jour. Agr. Research*, 4 (1915), No. 4, pp. 369-378, pls. 2).**—This fungus, which is parasitic on the false mistletoes, was first reported in New York and later in Michigan (*E. S. R.*, 13, p. 259). The author of the present article reports its frequent occurrence on the false mistletoe in Idaho and Montana. In addition to the species *Razoumofskya pusilla*, the host plant on which it was first discovered, the

author reports having observed the fungus on *R. americana* on *Pinus contorta*, and *R. douglasii* and its varieties on *Pseudotsuga taxifolia*, *Abies grandis*, *A. lasiocarpa*, and *Picea engelmanni*.

ECONOMIC ZOOLOGY—ENTOMOLOGY.

Elementary text-book of economic zoology and entomology, V. L. KELLOGG and R. W. DOANE (*New York: Henry Holt & Co., 1915, pp. X+532, figs. 246*)—This book is intended as a guide to students who wish to learn about animals from the special point of view of their interrelations with man. It is an introduction to general and economic zoology.

Studies in the longevity of insects, J. P. BAUMBERGER (*Ann. Ent. Soc. Amer., 7 (1914), No. 4, pp. 323-353, fig. 1*).—This article discusses the subjects of (1) longevity as affected by different constant temperatures (pp. 323-330); (2) longevity as affected by exposure to two different temperatures (pp. 330-338); and (3) hibernation as affected by exposure to two different temperatures (pp. 338-351).

A bibliography of 56 titles is included.

Key to the families of North American insects, C. T. BRUES and A. L. MELANDER (*Boston: Authors, 1915, pp. VII+140, figs. 427*).—In this manual the authors have attempted to bring together a brief yet complete key to all the families of American insects for the use of the general student.

A glossary of terms, drawings of anatomical details, and an index are included.

Injurious and beneficial insects of California, E. O. ESSIG (*Mo. Bul. Com. Hort. Cal., 4 (1915), No. 4, Sup., pp. LXXXI+541, figs. 503*).—A revised and enlarged edition of the work previously noted (*E. S. R., 28, p. 853*). The general scope of the work is practically the same, but many insects of minor importance have also been included, although household insects and those attacking domestic animals are largely omitted.

Materials for study of the injurious insects of the Government of Moscow, D. M. KOROLKOV (*Mat. po Izuch. Vredn. Nasček. Moskov. Gub., 5 (1914), pp. 1-93; abs. in Rev. Appl. Ent., 2 (1914), Ser. A, No. 6, pp. 366-370*).—This is a report on insects investigated by the author in an experimental orchard leased for that purpose. Among the pests considered are *Aporia cratagi*, *Anthonomus pomorum*, *Psylla mali*, *Byturus tomentosus*, the codling moth, *Incurvaria rubicella*, *Zophodia convolutella*, etc.

Fungus diseases and insect pests noticed in 1913 on the south coast of the Crimea and in the region of Balaklava, V. I. TUPIZIN (*Věstník Vinodětel., No. 4 (1914), pp. 226-231; abs. in Rev. Appl. Ent., 2 (1914), Ser. A, No. 6, pp. 354-355*).—The insects mentioned as having caused the most severe injury in 1913 are *Otiorynchus tauricus*, cutworms (*Agrotis*), *Pseudococcus vitis*, and *P. adonidum (longispinus)*.

Deformed apples and the causes, L. CAESAR (*Canad. Ent., 47 (1915), No. 2, pp. 49-54, figs. 4*).—A brief account is given of the plum curculio, apple curculio, leaf bugs or capsids, aphidids, apple maggot or railroad worm, and leaf rollers and green fruit worms, and the way they cause the malformations of apples.

The control of insect enemies of the vine, L. BERNARD (*Technique des Traitements contre les Insectes de la Vigne. Paris: J. B. Baillière & Sons, 1914, pp. VIII+364, figs. 95; abs. in Rev. Appl. Ent., 2 (1914), Ser. A, No. 10, pp. 607-609*).—The first part (pp. 1-46) of this work deals with the cochylis and eudemis moths, their history, geographical distribution, characteristics as distinguished from the pyralid moth, and biology. Part 2 (pp. 47-286) deals with

the control of these two pests, including both natural enemies and mechanical and chemical means. The third part (pp. 287-360) treats of other vine insects, of which 20 are dealt with, including 4 lepidopterans, 10 coleopterans, 1 orthopteran, 4 hemipterans, and 1 dipteran.

Hyponomeuta malinellus and *Carpocapsa pomonella*, N. BRUNNER (*Prog. Sadovod. i Ogorodnich.*, 1914, Nos. 27, pp. 870-872; 28, pp. 887, 888; 31, pp. 951-955, fig. 1; abs. in *Rev. Appl. Ent.*, 2 (1914), Ser. A, No. 11, p. 647).—A general account of these pests, their occurrence, and control measures employed in orchards of various districts of the Government of Ekaterinoslav.

The tree crickets of New York: Life history and bionomics, B. B. FULTON (*New York State Sta. Tech. Bul.* 42 (1915), pp. 3-47, pls. 6, figs. 21).—During the course of studies dealing with the economic aspects of tree crickets, accounts relating to which have been previously noted (E. S. R., 31, p. 649), observations were extended to several other species which do not attack cultivated crops, the results of which have been brought together in this bulletin.

An account is first given of the general characteristics of tree crickets, including general descriptions of life stages of *Oecanthus*, hatching, molting, feeding habits, digestive organs, musical organs and song production, mating habits, metanotal gland, description of the spermatophore, male reproductive organs, formation of the spermatophore, female reproductive organs, and oviposition. A key is next given to eggs and oviposition habits of eight species of tree crickets, namely, *O. nireus*, *O. angustipennis*, *O. exclamationis*, *O. quadripunctatus*, *O. nigricornis*, *O. pini*, *O. latipennis*, and *Neoxabca bipunctata*. The account of each of these species includes descriptions of life stages and habits so far as known.

A list of 50 titles of literature relating to the subject is included.

The destruction of *Stauronotus maroccanus* in Algeria by means of *Coccobacillus acridiorum*, M. BÉGUET (*Bul. Soc. Path. Exot.*, 7 (1914), No. 8-9, pp. 651-653; abs. in *Rev. Appl. Ent.*, 3 (1915), Ser. A, No. 3, p. 118).—A report of further work with *C. acridiorum* in Algeria (E. S. R., 31, p. 753).

Morphological studies on the head and mouth parts of the Thysanoptera, A. PETERSON (*Ann. Ent. Soc. Amer.*, 8 (1915), No. 1, pp. 20-66, figs. 61).—A detailed report of anatomical studies.

Experiments in the control of *Lecanium cerasi*, N. OSSIPOV (*Sadovod*, No. 7 (1914), pp. 514-521; abs. in *Rev. Appl. Ent.*, 2 (1914), Ser. A, No. 11, pp. 650, 651).—This is a report of control work with *Eulecanium cerasi* conducted during 1912 and 1913 in the districts of Chotin and Kishenef of the Government of Bessarabia.

New species of Coccidæ collected in Italy, G. LEONARDI (*Bol. Lab. Zool. Gen. e Agr. R. Scuola Sup. Agr. Portici*, 7 (1913), pp. 59-65, figs. 5).—*Pseudococcus grassii* collected on bananas purchased in Rome, *Aspidiotus viticola* on the grape, and *Aonidiella inopinata* on the almond in the Province of Syracuse, Sicily, are described as new.

On possible poisoning of insectivorous birds in the war against the gipsy moth, L. O. HOWARD (*Proc. Ent. Soc. Wash.*, 17 (1915), No. 1, p. 2).—It is stated that as a result of a search for dead birds by agents of the Bureau of Entomology of the U. S. Department of Agriculture in New England but one had been found up to September and that its stomach showed no trace of arsenic.

Dispersion of gipsy moth larvæ by the wind, C. W. COLLINS (*U. S. Dept. Agr. Bul.* 273 (1915), pp. 23, pls. 7).—This is a detailed report of investigations of the dispersion of the gipsy moth by wind, in continuation of those by Burgess previously noted (E. S. R., 28, p. 655), in which large scale screen experiments were conducted at Salisbury Beach, Merrimac, Plum Island, Mass.,

on the Isles of Shoals, N. H., and on the hills of New Hampshire. Brief notes are first presented in regard to the structure and function of acuminate and vesicular hairs.

"In 1913 as a result of the several experiments conducted by using tangle-footed screens and cloth for traps, there were caught on 977 sq. ft. 289 first-stage larvæ which had been borne by the wind one-eighth to 1 mile or more. In 1914 there were removed from 1,614 sq. ft. of sticky surface 346 larvæ which had been blown from one-eighth to 13.5 miles or more, as verified by the wind records taken at or near those points. Three larvæ were also taken from two large screens on the hills in New Hampshire during 1914.

"Considering the great numbers of larvæ taken in these experiments, there can be no doubt that the wind is almost wholly responsible for the general spread of this insect in New England, notwithstanding the fact that many of the former publications teem with explanations of possible accidental or artificial spread by man and animals. . . . To prevent continual spread by the wind into new territory the badly infested areas near the border must be brought under control either by natural enemies, or hand methods, or both. Natural enemies, however, are now playing an important rôle in the control of this insect in the greater area of the inside infested territory.

"The larvæ are sufficiently active and allow themselves to be transported by the wind at temperatures of 55° F. and above, and have been caught at wind velocities varying from 2 to 23 miles per hour, although more active spread takes place when the temperature ranges from 65 to 85° and when the velocity reaches 8 miles or more per hour. Larvæ are removed from their support and carried by sudden gusts of wind, whether they spin or not, when the temperature reaches 50 to 55°, at which temperatures they often start crawling.

"The records also show that larvæ have been caught at times when winds were blowing from all directions except the North—only a very few coming from the East, but the location of the screens along and near the coast materially affected this condition. By far the larger number were borne by combinations of the west winds, as indicated on the screen at Merrimac, Mass., which was surrounded by a general infestation.

"The general progress of the species since its establishment at Medford, Mass., at the rate of 5 miles per year to the northeast and at the rate of 3 miles per year westward from Providence, R. I., since its first appearance there in 1901 tends to verify the data that have been collected in connection with the screen experiments."

A list of 8 references to the subject and a large size map showing the dispersion of the gipsy moth in New England and area quarantined in 1914 are included.

The millet caterpillar, A. HEMPEL (*Fazendeiro, Sao Paulo. 7 (1914), No. 3, p. 110; abs. in Rev. Appl. Ent., 2 (1914), Ser. A, No. 11, p. 627*).—The larva of *Remigia repanda*, known in Brazil for at least 12 years, has recently appeared in many parts of the country and a general invasion of this important pest is feared.

Control of the army cutworm, R. A. COOLEY (*Montana Sta. Circ. 47 (1915), pp. 1-3*).—Since Circular 4 on the army cutworm was issued (E. S. R., 23, p. 363) particular success has been met with in controlling outbreaks of this pest through the use of poisoned bran mash.

Notes by A. Atkinson on crops to plant where winter wheat has been destroyed by cutworms are appended.

Problems relating to the new pest of Egyptian cotton, the pink bollworm (*Gelechia gossypiella*), L. H. GOUGH (*Bul. Union Agr. Égypte*, 12 (1914), No. 107, pp. 196, 197; *abs. in Rev. Appl. Ent.*, 2 (1914), Ser. A, No. 10, p. 596).—The author reports that the number of generations per annum of the pink bollworm in Egypt varies from one to six. After the growth of the larvæ has been completed a hibernation or estivation of from one week to an indefinite time may take place before they transform to pupæ.

Four natural enemies, namely, *Pimpla roborator*, *Chelonella sulcata*, *Limnerium interruptum*, and *Pediculoides ventricosus*, together with *Microsporidium polyhedricum*, are capable of reducing the number of hibernating larvæ to 40 per cent or less.

An enemy of cultivated carnations, MOLINAS (*Bul. Soc. Nat. Agr. France*, 74 (1914), No. 4, pp. 476-481; *abs. in Rev. Appl. Ent.*, 2 (1914), Ser. A, No. 10, p. 620).—The tortricid moth *Tortrix pronubana*, of which there are four generations annually, is said to attack frequently carnations cultivated on the coasts of Provence and of Italy. The species, though quite polyphagous and found in the greater part of France on indigenous plants belonging to widely separate families, has not been reported a source of injury to cultivated plants. As high as 400 eggs may be deposited in batches of from 30 to 80 eggs. The larvæ live in the leaves and flowers. Several parasites which are important aids in its control have been reared by the author. Fumigation has not been found to be effective and hand destruction has to be resorted to. See also a previous note (*E. S. R.*, 30, p. 356).

Life history of *Eucosma haracana*, A. BUSCK (*Proc. Ent. Soc. Wash.*, 16 (1914), No. 4, p. 150, pl. 1).—The notes here presented relate to a lepidopterous leaf roller on chestnut in the vicinity of Washington, D. C.

Leaf miner of citrus (*Phyllocnistis citrella*), A. RUTHERFORD (*Trop. Agr. [Ceylon]*, 43 (1914), No. 1, pp. 49, 50; *abs. in Rev. Appl. Ent.*, 2 (1914), Ser. A, No. 11, pp. 651, 652).—This tineid mines in the young twigs and young leaves of citrus trees in Ceylon.

Life histories of North American Tineina, ANNETTE F. BRAUN (*Canad. Ent.*, 47 (1915), No. 4, pp. 104-108).—The biological notes here presented relate to *Choreutis inflatella*, the larva of which feeds on the leaves of *Scutellaria latriflora*; *Aristotelia salicifungicella*, which feeds on the leaves of *Salix longifolia*; *Recurvaria dorsivittella*, which feeds on the sweet gum (*Liquidambar styraciflua*); *Elachista pralinata* n. sp., which mines in the leaves of *Hystrix patula*; *Theisoa constrictella*, which feeds under a web on the lower surface of the leaves of the white elm (*Ulmus americana*) and cork elm (*U. racemosa*); and *Psacaphora engelcella*, which mines the leaves of *Circæa lutetiana*.

Descriptions of new Microlepidoptera of forest trees, A. BUSCK (*Proc. Ent. Soc. Wash.*, 16 (1914), No. 4, pp. 143-150, pls. 2).—The species of economic importance here described as new are *Sesia brunneri* on *Pinus ponderosa* at Camas, Mont.; *Recurvaria milleri* on *P. murrayana* in the Yosemite National Park, California; *Exctria bushnelli* on *P. ponderosa* and other pines at Fort Bayard, N. Mex.; *E. virginiana* on *P. virginiana* at Falls Church, Va.; *E. taxifoliella* on *Pseudotsuga taxifolia* at Missoula, Mont.; *E. metallica* on *P. ponderosa* at Missoula, Mont.; *E. montana* on *P. contorta* at Elliston, Mont.; *E. albicapitana* on *P. divaricata* at MacDowell, Saskatchewan, and at Boulder Junction, Wis.; *Sicammerdamia castaneæ* on *Castanea dentata* at East River, Conn., and Charter Oak, Pa.; and *Ectædemia heinrichi* on *Quercus palustris* at Falls Church, Va.

On *Mnemonica auricyanea*, A. BUSCK and A. BÖVING (*Proc. Ent. Soc. Wash.*, 16 (1914), No. 4, pp. 151-163, pls. 8).—Notes are given on the biology and results

of an anatomical study of *M. auricyanea*, the larva of which is a leaf miner on the chestnut, oak, and chinquapin. The eggs are deposited in May. The larva completes its feeding within a week or ten days and then drops to the ground. Into which it burrows to as great a depth as 1 ft. It remains spun up in a cocoon during the summer and fall, and transforms to a pupa during the winter. Thus more than eleven months of each year of its life are spent underground.

On *Acrocercops strigifinitella*, C. HEINRICH and J. J. DEGRYSE (*Proc. Ent. Soc. Wash.*, 17 (1915), No. 1, pp. 6-23, figs. 31).—The larva of this lepidopteran has been found to mine the midribs of chestnut, chinquapin, and oak leaves at Falls Church, Va. Descriptions are given of its structure, stages, and habits. Chestnut appears to be the favorite food plant and during midsummer the work of the species is very common; few of the young leaves escape infestation and some bear as many as four separate mines. There are a number of generations with considerable overlapping so that larvæ are to be found at any time from May until well into October.

The small winter moth (*Cheimatobia brumata*) (*Inst. Phytopath. Wageningen, Vlugschr.* 14 (1914), pp. 3; *abs. in Rev. Appl. Ent.*, 2 (1914), Ser. A, No. 11, p. 642).—This lepidopteran is a widespread pest in Holland in orchards, nurseries, and forests.

Malaria: Lessons on its cause and prevention, H. R. CARTER (*Pub. Health Rpts. [U. S.]*, Sup. 18 (1914), pp. 20, pls. 4).—This paper, prepared for use in schools, deals in large part with mosquitoes and their rôle in the transmission of malaria and the means of prevention of the disease through the control of anopheline mosquitoes.

Control of malaria: Oiling as an antimosquito measure, J. A. A. LE PRINCE (*Pub. Health Rpts. [U. S.]*, 30 (1915), No. 9, pp. 599-608, figs. 5).—The author states that oiling of water surfaces as an antimalaria measure should be supplementary to proper drainage, but that where funds are not available for drainage mosquito propagation can be largely controlled by oiling. He states that there are many grades of oil suitable for mosquito destruction ranging from the very light oils such as kerosene to the heavier or crude oils. The advantage of the lighter oils is that they form a thin film which spreads rapidly. Apparatus and methods for oiling water surfaces of pools, ditches, streams, etc., are described and illustrated.

Some new observations on the life history of warble flies, G. H. CARPENTER and T. R. HEWITT (*Irish Nat.*, 23 (1914), No. 10, pp. 214-221; *abs. in Rev. Appl. Ent.*, 3 (1915), Ser. B, No. 2, p. 19).—These data relating to the entrance of the larva into the host's body have been previously noted from another source (*E. R. S.*, 32, p. 680).

Notes on the pupation of the house fly (*Musca domestica*) and its mode of overwintering, C. G. HEWITT (*Canad. Ent.*, 47 (1915), No. 3, pp. 73-78, fig. 1).—The results of careful investigations of soil subjacent to heaps of manure, made with a view to determining the distances and depth to which house fly larvæ migrate prior to pupation, are reported upon and diagrammatically illustrated. "A few puparia were found directly beneath the manure pile to a depth of 12 in. The greatest numbers occurred in the region about 18 in. from the pile and at a depth of 12 in. to 2 ft. from the surface . . . the puparia were also numerous immediately below the surface of the soil. The numbers then gradually decreased proportional to the distance from the pile and dwindled away at a distance of about 4 ft. from its base."

As regards the overwintering of the house fly, the author states that in no case has he been able to find living pupæ of *M. domestica* under outdoor condi-

tions during the winter in either England or Canada. Neither has it been possible in breeding experiments in Canada or England to carry it through the winter in the pupal stage. He recognizes the possibility, however, that it may do so in a more southern latitude.

The larva and puparium of the frit fly, T. R. HEWITT (*Sci. Proc. Roy. Dublin Soc., n. ser., 14 (1914), No. 23, pp. 313-316, pl. 1*).—A detailed description of the early stages of *Oscinis frit*, one of the worst cereal pests in Europe and common in the British Isles, particularly in several counties of Ireland.

Fleas, F. C. BISHOPP (*U. S. Dept. Agr. Bul. 248 (1915), pp. 31, figs. 9*).—A popular summarized account of fleas, including their biology, host and disease relations, and control and remedial measures.

The May beetle in Bukowina and the conditions favoring its dissemination in central Europe, F. ZWEIFELT (*Naturw. Ztschr. Forst u. Landw., 12 (1914), Nos. 6, pp. 265-291; 7, pp. 329-344, figs. 4; abs. in Rev. Appl. Ent., 2 (1914), Ser. A, No. 11, p. 640*).—This is a discussion of the occurrence of May beetles (*Melolontha vulgaris* and *M. hippocastani*) in eastern Austria-Hungary, and particularly the outbreak of 1912, their injury, climatic and other conditions influencing their increase and spread, control measures, etc. A bibliography of 9 titles is appended.

Occurrence and distribution of the May beetle in lower Austria in 1913, F. ZWEIFELT (*Mitt. Bot. Versuchslab. u. Lab. Pflanzenkrank. K. K. Ünol.-Pomol. Inst. Klosterneuburg, n. ser., No. 5 (1914), pp. 16, figs. 3*).—This is supplementary to the account above noted.

Laboulbeniales parasitic on Chrysomelidæ, R. THAXTER (*Proc. Amer. Acad. Arts and Sci., 50 (1914), No. 2, pp. 17-50*).—Thirty-one new species, parasitic on leaf-feeding beetles and collected from various regions in the Tropics, are described as new. While a great majority of the chrysomelid parasites belong to the genus *Laboulbenia*, two other genera are represented by well-marked forms, namely, *Dimocromyces*, contributing four species from Mexico, the West Indies, and the Straits Settlements; and *Ceraomyces*, including seven species, six of which are parasitic on flea-beetles from the West Indies and Brazil and the seventh a very peculiar form from Kamerun and Madagascar.

Borer pests of *Ficus elastica*, K. W. DAMMERMAN (*Dept. Landb., Nijv. en Handel [Dutch East Indies], Meded. Afdel. Plantenziekten, No. 7 (1913), pp. 48, pls. 4, figs. 2; abs. in Rev. Appl. Ent., 2 (1914), Ser. A, No. 9, pp. 533-536*).—A report of studies of the coleopterous borers of the rubber plant (*F. elastica*) in Java, including 11 species of Cerambycidae and 2 of Curculionidæ.

Some experiments on the control of wireworms (Elateridæ and Opatridæ) (*Trudy Bessarabsk. Obshch. Estest. i Lûubit. Estest., 3 (1911-12), pp. 135-146*).—A brief report of experiments in the protection of corn seed from, and the destruction of, wireworms of the genera *Corymbites* and *Opatrum*.

The soaking of seed corn in petroleum for as long as 20 minutes did not protect it from wireworm attack. In a series of tests, in which corn coated with powdered arsenicals, etc., was used as a bait, it was found that white arsenic killed 87 per cent of the wireworms in 21 days, Paris green 76 per cent in 16 days, barium chlorid 72 per cent in 19 days, and corrosive sublimate 65 per cent in 18 days.

The principal insects injurious to lucern.—II, *Otiorynchus (Cryphiphorus) ligustici*, its description, life habits, and methods of combating it, I. V. VASSILIEV (*Abs. in Rev. Appl. Ent., 2 (1914), Ser. A, No. 11, pp. 668, 669*).—This is the second part of a work on insect enemies of alfalfa, the first having dealt with *Adelphocoris lineolatus*.

O. ligustici is found everywhere in Europe, except in the more southern parts, and as far east as Tobolsk, Russia. The larvæ at first make unimpor-

tant wounds in the collars of the plant, but soon burrow deeper in the soil and attack the roots. The depth to which they burrow varies from the surface to 20 in., according to the amount of moisture in the soil, etc.

On some Curculionidæ living in bamboo stems, A. DA COSTA LIMA (*Mem. Inst. Oswaldo Cruz*, 6 (1914), No. 3, pp. 224-230, pls. 2).—In this second paper (E. S. R., 32, p. 352) the author deals at some length with *Astyage lineigera*, a curculionid beetle attacking bamboo in Brazil. The larvæ and nymphs of this species are said to be attacked by flacherie, which is responsible for a large mortality. Other species reared from bamboo stems at Joinville are *Peridercus granellus*, *Dionychus parallelogramus*, and *Erethistes lateralis catharinensis*.

Inquiline bumblebees in British Columbia, F. W. L. SLADEN (*Canad. Ent.*, 47 (1915), No. 3, p. 84).—The author records the collection of *Psithyrus insularis* and *P. consultus* in a nest of *Bombus flavifrons* at Agassiz, British Columbia, upon which they are apparently parasitic.

Description of a new seed chalcid from spruce, S. A. ROHWER (*Canad. Ent.*, 47 (1915), No. 3, pp. 97, 98, fig. 1).—A chalcidid reared from the seeds of Engelmann spruce (*Picea engelmanni*), the Sitka spruce (*P. sitchensis*), and the Colorado blue spruce (*P. parryana*) in Colorado, and also received from California, is described as *Megastigmus piceæ*.

Asparagus beetle egg parasite, F. A. JOHNSTON (*U. S. Dept. Agr., Jour. Agr. Research*, 4 (1915), No. 4, pp. 303-313, pl. 1).—This report of studies of *Tetrastichus asparagi* includes a summary of those of Russell and Johnston, previously noted (E. S. R., 28, p. 858).

Following a brief introduction, descriptions are given of the several stages of the parasite, its distribution, and feeding habits. Under the heading of laboratory experiments, a brief account is given of methods used in rearing the parasite and a tabulation of records of the length of life of the adult in confinement. There appear to be three generations a year on Long Island, where it apparently hibernates as a full-grown larva in the cell of its host in the ground. In rearing experiments from 1 to 10 larvæ of the parasite were found in a single beetle cell. Attempted parasitism of the eggs and young larvæ of the potato beetle and eggs of the elm-leaf beetle failed. From 7 to 11 days were found to be passed in the pupal stage.

A list of 7 titles is given of literature cited.

Notes on the life history of a species of wasplike parasites of the genus *Leptomastix*, parasitic on the mealy bug, H. L. VIERECK (*Mo. Bul. Com. Hort. Cal.*, 4 (1915), No. 4, pp. 208-211, figs. 3).—A chalcidid belonging to the genus *Leptomastix* which appears to be new to science was collected by the author on *Pseudococcus citri* at Palermo, Sicily, in June, 1914. It has since been introduced into California, where it has been successfully reared and bids fair to become an important aid in the control of the citrus mealy bug.

Studies of its life history show that from 21 to 49 days are required to pass from the laying of the egg to the emergence of the adult. From 3 to 6 days are passed in the egg stage, from 8 to 25 days in the larval stage, and from 10 to 18 days in the pupal stage.

Journey in Eritrea in search of olive fly parasites, F. SILVESTRI (*Bol. Lab. Zool. Gen. e Agr. R. Scuola Sup. Agr. Portici*, 9 (1914), pp. 186-226, figs. 24; *abs. in Rev. Appl. Ent.*, 3 (1915), Ser. A, No. 4, p. 173).—As a result of a trip to Eritrea during August and September, 1914, 14 parasites of the olive fly (*Dacus oleæ*) were secured. Descriptions and biological notes are given.

Parasitic Hymenoptera new to the fauna of Turkestan, N. KOKUEV (*Russ. Ent. Obozr.*, 13 (1913), No. 3-4, pp. 513, 514).—The author describes *Habrobracon*

simonovi, reared from the hollworm (*Chloridea obsoleta* [*Heliothis armigera*]); and *Chelonus caradrinæ* and *Microplites rufiventris*, reared from larvæ of *Caradrina crigua*, all from Tashkend, as new to science.

Injury caused by *Janus luteipes* in osiers. W. BAER (*Naturw. Ztschr. Forst u. Landw.*, 12 (1914), No. 6, pp. 292-294; *abs. in Rev. Appl. Ent.*, 2 (1914), Ser. A, No. 11, pp. 642, 643).—This sawfly is a source of considerable injury to osiers in the Tharandt district through boring in the stems.

The yellow gooseberry sawfly. L. FULMEK (*Reprint from Obstzüchter*, No. 6 (1914), pp. 4, figs. 2; *abs. in Rev. Appl. Ent.*, 2 (1914), Ser. A, No. 10, p. 590).—An account of *Pteronus ribesii* and means for its control.

An imported red spider attacking fruit trees. L. CAESAR (*Canad. Ent.*, 47 (1915), No. 2, pp. 57, 58, figs. 2).—*Tetranychus pilosus*, a European species that attacks fruit trees and is closely related to and perhaps identical with *T. mytilaspidis* which feeds chiefly on oranges, has been found to occur commonly on fruit trees in Ontario. The foliage of badly infested trees becomes covered with numerous fine whitish blotches very noticeable on the upper surface and after a time turns brown.

Four new tetranychids. E. A. MCGREGOR (*Ann. Ent. Soc. Amer.*, 7 (1914), No. 4, pp. 354-364, figs. 27).—Four phytophagous mites from the southeastern United States, said to be of considerable economic importance, are described as *Tenuipalpus bioculatus* from privet, strawberry, and other plants at Batesburg, S. C., and Baton Rouge, La.; *Tetranychus yothersi* from camphor and eucalypts at Orlando, Fla., and elm, oak, and pecans at Batesburg, S. C., etc.; *T. banksi* from castor beans and velvet beans at Orlando, Fla.; and *T. quinquenychus* from castor beans at Orlando, Fla.

The beaver fluke (*Amphistomum subtriquetrum*). DOROTHY DUFF (*Proc. and Trans. Roy. Soc. Canada*, 3. ser., 8 (1914), Sect. IV, pp. 87-98, pls. 4).—A report of an anatomical and histological study of this fluke. A list of references to the literature cited is appended.

Leeches: Exotic leeches. A. E. SHIPLEY (*Brit. Med. Jour.*, No. 2814 (1914), pp. 962-964, figs. 6).—A brief account of leeches of importance.

FOODS—HUMAN NUTRITION.

Milling and baking qualities of Victorian wheats. A. E. V. RICHARDSON, P. R. SCOTT, and F. G. B. WINSLOW (*Jour. Dept. Agr. Victoria*, 12 (1914), No. 11, pp. 668-675).—In continuation of previous work (*E. S. R.*, 32, p. 659), the authors report a study of the milling and baking qualities of wheat grown under different soil and climatic conditions.

Regardless of the conditions under which they were cultivated, the same varieties showed the same relative differences in the quality of the grain. In chemical composition it is thought that seasonal conditions and soil are important in determining quality. The varieties of highest milling quality were the least prolific growers, and vice versa.

The gluten content of flours. M. H. HITIER (*Bul. Soc. Encour. Indus. Nat. [Paris]*, 121 (1914), No. 1, pp. 76-87).—A summary and digest of data which considers the variation, during different years and in different countries, of the gluten content of flours. The variety of seed, kind of soil, and cultivation, and, most important of all, the influence of climatic conditions, are the factors attributed by the author to the steadily decreasing gluten content in French wheats especially noticeable during recent years.

Bread. K. SCHERINGA (*Chem. Weekbl.*, 11 (1914), No. 51, p. 1074).—Chemical examinations of bread are reported which indicate that the fiber content depends

upon the origin of the grain and also upon the method of milling. The pentosan content of bread appeared to vary considerably.

Studies of poultry from the farm to the consumer, MARY E. PENNINGTON (*U. S. Dept. Agr., Bur. Chem. Circ. 64, reprint (1915), pp. 42, figs. 9*).—In this reprint (*E. S. R., 24, p. 361*) a few changes as to storage temperatures have been made.

Cured fish, P. BUTTENBERG and L. VON NOËL (*Ztschr. Untersuch. Nahr. u. Genussmtl., 30 (1915), No. 1, pp. 1-15*).—Methods are described for curing fish, and the results are reported of analyses of several products cured in different ways.

Some new constituents of milk.—I, The phosphatids of milk, T. B. OSBORNE and A. J. WAKEMAN (*Jour. Biol. Chem., 21 (1915), No. 3, pp. 539-550*).—This paper describes in detail the chemical and physical properties of two phosphatids separated from milk by the authors. The experimental procedure followed is described in detail.

Human milk, A. W. BOSWORTH (*New York State Sta. Tech. Bul. 43 (1915), pp. 5; Jour. Biol. Chem., 20 (1915), No. 4, pp. 707-709*).—In extension of earlier work and employing methods previously described (*E. S. R., 32, p. 607*), an investigation was made of the chemical composition of human milk.

The author states that "the high acid figures previously obtained for cow's milk were due to the interference of the neutral calcium phosphate, CaHPO_4 , which is present in cow's milk but not in human milk." The results of this study indicate that, contrary to the prevailing idea, the acidity of human milk and cow's milk is practically the same, and "the practice of adding lime water to modified cow's milk used for infant feeding as a means of correcting the acidity is thus shown to have no foundation. . . ."

"It was found impossible to separate the calcium from the protein by any mechanical means; so we conclude that it is in chemical combination with the protein. It is important to note that evidence seems to indicate that the albumin as well as the casein is combined with calcium. This will be investigated more carefully before any definite report is made."

Unlike cow's milk, human milk contains no insoluble inorganic phosphates. The following figures are given as representing the probable average composition of human milk: Fat, 3.3 per cent; calcium chlorid, 0.059 per cent; milk sugar, 6.5 per cent; proteins combined with calcium, 1.5 per cent; monopotassium phosphate ($\text{KH}_2\text{P}_2\text{O}_7$), 0.069 per cent; sodium citrate ($\text{Na}_3\text{C}_6\text{H}_5\text{O}_7$), 0.055 per cent; potassium citrate ($\text{K}_3\text{C}_6\text{H}_5\text{O}_7$), 0.103 per cent; and mono-magnesium phosphate ($\text{MgH}_2\text{P}_2\text{O}_7$), 0.027 per cent.

Soy bean milk (*Epicure, 21 (1914), No. 250, pp. 157, 158*).—This article describes briefly the manufacture of an artificial milk from soy beans, which it is claimed can be successfully used as a substitute for cow's milk. It is stated that, owing to its low degree of acidity, it will keep longer than cow's milk. The chemical composition of this product is given as follows: Fat, 3.5 per cent; casein and albumin, 3.5 per cent; carbohydrates, 4.25 per cent; salts (mineral matter), 0.75 per cent; and water, 88 per cent.

Vegetable butters (*Pure Products, 10 (1914), No. 11, pp. 550, 551*).—In this article are described several vegetable butters which it is claimed could possibly be substituted for butter and lard in cooking. The varieties described are Karite butter, a substance prepared from the seeds of a tree belonging to the family of Sapotaceæ, found principally in Africa and the East Indies; Illipe butter, prepared from two different species of the Sapotaceæ family, found principally in Hindustan; Dika butter, prepared from the seeds of the *Irvingia gabonensis* of the family of the Simaparoubia, found principally in the

Kongo region; and Muscade butter, extracted from the seeds of the *Myristica moschata*, grown on the Sonda Islands.

Changes in potatoes during drying, H. I. WATERMAN (*Chem. Weekbl.*, 12 (1915), No. 3, pp. 48, 49).—Analytical data are given from which the author concludes that, when dried at a moderate temperature, a part of the starch of potatoes is converted into sucrose. The amount of sucrose present when the drying was carried on at 35° C. was 3.3 per cent; at 45° it was 2.1 per cent; and at 55°, 1.6 per cent. The increased temperature did not alter the content of total or soluble nitrogen.

Tomato conserve, P. GUARNIERI (*Staz. Sper. Agr. Ital.*, 47 (1914), No. 7, pp. 474-480).—The results are given of analyses of extracts of preserved tomatoes with and without added preservative.

A tea from Asia Minor, T. F. HANAUSEK (*Ztschr. Untersuch. Nahr. u. Genussmtl.*, 28 (1914), No. 5, pp. 259-263, figs. 4).—This product, which is described in detail, is said to resemble genuine Chinese souchong. It is prepared from the leaves of *Origanum vulgare albiflorum* and is in general use in Asia Minor.

Tin in canned foods, ROSSÉE and VON MORGENSTERN (*Ztschr. Öffentl. Chem.*, 20 (1914), No. 9, pp. 171, 172).—The analytical data here reported may be summarized briefly as follows:

Canned vegetables contain traces of tin dissolved from the container. Larger amounts were found when the receptacle had been open for some time. According to the authors, since the dissolved tin forms insoluble substances with the vegetables and is not redissolved by the digestive juices, the ingestion of small amounts of tin from this source is not injurious to the body.

Methods of destroying vinegar eels, J. F. SACHER (*Chem. Ztg.*, 38 (1914), No. 99, pp. 1021, 1022; *abs. in Jour. Soc. Chem. Indus.*, 34 (1915), No. 4, pp. 193).—Out of 25 samples of vinegar collected in retail stores, 23 were found to be infested with vinegar eels.

It was found that they could be killed by heating the vinegar to 45° C. for a few minutes and removed by filtration. Exposure to bright sunlight for several hours or complete exclusion of air for several weeks was also fatal, but this method is only applicable to finished vinegar as *Mycodesma aceti* is also injured by light. If 2½ to 3 gm. of calcium carbonate was added to sealed bottles containing 400 cc. of vinegar the animalculæ died—it was thought from want of air. One per cent of common salt killed the organisms within 24 hours and 2½ per cent of sodium sulphate in 20 hours, but similar quantities of potassium salts had little effect. A summary of these and other tests seems to indicate that the toxic action of the sodium salts is due to the presence of the sodium ion. The poisonous effect of acids is also probably due to the concentration of the hydrogen ion. A concentration of 14 per cent of alcohol was also fatal to the eels.

Report of the department of food and drugs control, and weights and measures for the period ending December 31, 1914 (*Nevada Sta. Rpt. Dept. Food and Drugs Control, and Weights and Measures, 1914*, pp. 34).—A review of the work of the department in the sanitary inspection of dairies and restaurants and the chemical examination of miscellaneous samples of foods and drugs, together with the reports of local food inspectors and the department of weights and measures.

Twenty-ninth annual report of the dairy and food division (*Ann. Rpt. Dairy and Food Div. Ohio*, 29 (1914), pp. 175, figs. 7).—This report reviews the work of the dairy and food division for the year ended November 15, 1914. This included the sanitary inspection of dairies and other establishments where food is prepared, and the examination of foods and drugs. The texts

of the sanitary codes for the regulation of ice-cream factories, cheese factories, confectionery establishments, and bottling establishments are also given. The reports of the sealers of weights and measures and general data regarding the work constitute the bulk of the report.

[Food, drug, and paint laws], E. F. LADD (*North Dakota Sta. Spec. Bul. 6, reprint (1915), pp. 48*).—This publication contains the texts of the state food, drug, and paint laws, with rulings and discussions, as amended since the first issue. (E. S. R., 19, p. 113.)

State laws and regulations pertaining to public health adopted during the [years 1913 and 1914] (*Pub. Health Rpts. [U. S.], 1915, Reprints 264, pp. 539; 279, pp. 190*).—In these publications is given the text of legislative enactments regulating the sanitary condition of places where food is manufactured, stored, sold, or handled.

The nutrition of a household, E. T. and LILIAN BREWSTER (*Boston: Houghton Mifflin Co., 1915, pp. X+208*).—In this book the authors bring together a great deal of useful information in a form which should make it available to non-technical readers. Fundamental principles of human nutrition are considered in the light of the work of various investigators, and different dietetic standards are discussed. An appendix contains tables showing the energy furnished by standard amounts of the more common food materials.

How to cook and why, ELIZABETH CONDIT and JESSIE A. LONG (*New York and London: Harper & Bros., 1914, pp. II+249, figs. 16*).—This book is intended for the use of housekeepers and students in domestic science and treats of both food values and food costs. The different groups of food materials (cereals, breads, pastries, fruit, dairy products, meat, etc.) are considered from the standpoint of chemical composition, food value, and relative cost as sources of nutriment.

Information regarding the selection, preparation, cooking, and serving of different foods; a few recipes; and hints regarding the combining of foods and the keeping of foods in the home are also given.

Household accounting, LAURA COMSTOCK (*Agr. of Mass., 62 (1914), pp. 78-90*).—In this address consideration is given to the proportion of the income which should be spent for food as well as for other household expenses. Methods of keeping accounts are also considered to some extent.

Nutrition of workmen in cities with reference to protein requirement, F. HIRSCHFELD (*Deut. Med. Wchnschr., 41 (1915), No. 9, pp. 244-248*).—Two dietary studies are reported in which special attention was given to the protein requirements of two subjects engaged in moderately hard muscular work. A critical discussion of the article by M. Rubner is appended.

The diet of the herdsmen in two counties near Innsbruck in the higher Alps, L. E. VON CEIPEK (*Wiener Klin. Wchnschr., 27 (1914), No. 21, pp. 703-709*).—A dietary study of two herdsmen showed that on an average they ate, respectively, 176 and 213 gm. of protein, 307 and 318 gm. of fat, and 537 and 541 gm. of carbohydrates daily, which supplied 5,636 and 6,107 calories. Over half of the protein eaten was of animal origin.

Studies of the etiology of pellagra, CARPONE and CAZZAMALLI (*Gior. R. Soc. Ital. Ig., 36 (1914), Nos. 1, pp. 4-14; 2, pp. 51-63; 3, pp. 99-109; 4, pp. 151-156; abs. in Zentbl. Biochem. u. Biophys., 17 (1915), No. 16, pp. 635, 636*).—Experiments are reported in which were studied the effects of feeding mice sterilized maize, maize infected with pathogenic bacteria, and maize containing toxic products of nonpathogens. The results would seem to support the theory that toxic substances in the maize produce pellagra.

The exclusive maize feeding of animals, J. J. NITZESCO (*Compt. Rend. Soc. Biol., [Paris], 78 (1915), No. 8, pp. 222-224*).—Experimental feeding of dogs

during a 3-month period is the basis for the author's conclusion that the insufficiency of the maize diet and intoxication with zein (zeinolytic ferments were found in the blood) are to be considered among the principal causes of pellagra.

Influence of fat on the gastric digestion of milk. D. S. RIVA ROCCI (*Pediatrics [Naples]*, 22 (1914), No. 7, pp. 487-494).—From the results of a number of digestion experiments here reported the conclusion is drawn that the presence of fat aids rather than hinders the digestion of the protein of milk.

The effect of fats and carbohydrates upon nitrogen excretion during protein starvation. H. ZELLER (*Arch. Anat. u. Physiol., Physiol. Abt.*, No. 3-4 (1914), pp. 213-236; *abs. in Zeitbl. Biochem. u. Biophys.*, 17 (1914), No. 13, pp. 482, 483).—Experimental data are reported which may be summarized in part as follows:

A replacing of from 70 to 90 per cent of the carbohydrates in the diet with an equivalent (isodynamic) amount of fat did not result in exceeding the minimum of nitrogen excretion of a pure carbohydrate diet. In the opinion of the author, to secure complete combustion of the fat the ratio of fat to carbohydrate must be at least 4:1. The excretion of creatin and creatinin was the same in the case of pure carbohydrate and pure fat diets. The increase in the excretion of nitrogen noted during maintenance upon a pure fat diet apparently depended upon an increased destruction of protein.

The influence of starch on infant digestion. T. S. SOUTHWORTH (*Jour. Amer. Med. Assoc.*, 63 (1914), No. 16, pp. 1375-1377).—The results of clinical experiences are given, from which the inference is drawn that with those infants suffering from digestive and nutritional disturbances the principal benefit to be derived from the addition of starch to their food is not only to nourish the infant but to make possible a more orderly digestion of its main nutriment, milk.

The influence of lactose on the metabolism of an infant. F. B. TALBOT and L. W. HILL (*Amer. Jour. Diseases Children*, 8 (1914), No. 3, pp. 218-227, fig. 1).—A metabolism experiment with an infant five months of age is reported from which the conclusions drawn are in part as follows:

"Increasing amounts of sugar up to a certain limit increase the retention of nitrogen, and beyond that point may diminish the absorption and possibly the retention of nitrogen. Increasing amounts of sugar do not affect the absorption of fat up to a certain point, beyond which point there may be a diminished absorption of fat."

Excessive amounts of lactose produced digestive disturbances.

Creatinin and creatin in starvation. G. GRAHAM and E. P. POULTON (*Jour. Physiol.*, 48 (1914), No. 5, pp. LIII, LIV).—The results are reported of two fasting experiments which indicate that traces of "true" creatin are excreted during absolute starvation lasting for three days.

Studies in endogenous uric acid metabolism. G. W. RAIZISS, H. DUBIN, and A. I. RINGER (*Jour. Biol. Chem.*, 19 (1914), No. 4, pp. 473-485).—A study of the uric acid excretion of 10 individuals on a meat-free diet gave results considerably lower than values reported by other investigators. It was found that under the same conditions of diet and rest different individuals eliminated practically the same amount of uric acid daily. An increase in uric acid excretion was produced by work and a high protein intake. After changing from a mixed diet to a vegetable and meat-free diet the amount of uric acid eliminated was smaller, though for the first few days it increased somewhat—due probably to the excretion of accumulated purin in the body.

Lipins in nutrition. C. G. MCARTHUR and C. L. LUCKETT (*Jour. Biol. Chem.*, 20 (1915), No. 2, pp. 161-174, figs. 3).—The results of feeding experiments with laboratory animals (mice) are summarized by the authors as follows.

"Lecithin, cephalin, cerebroside, cholesterol, and fats are dispensable parts of a food for mice, but a substance is present in egg yolk [which is], insoluble in ether, soluble in cold alcohol, and probably easily destroyed by heat, that needs to be added to a synthetic food containing casein, starch, lactose, lard, and the salts of milk, to make it a complete food."

The therapeutic value of organic phosphorus compounds. E. K. MARSHALL, JR. (*Jour. Amer. Med. Assoc.*, 64 (1915), No. 7, pp. 573, 574).—A digest of experimental data which support the view that the animal organism can synthesize its complex organic phosphorus constituents from inorganic phosphates in the food.

Studies of unbalanced diet.—II. Water distribution and edema following the addition of salts to the diet. P. TACHAU (*Biochem. Ztschr.*, 67 (1914), No. 4-5, pp. 333-343).—The addition, in gradually increasing quantities, of inorganic salts (sodium chlorid, sodium phosphate, and sodium lactate) to the diet of laboratory animals (mice) appeared to have no influence upon the total water content of the body, although it led to the occurrence of edema. The cause of the edema was believed to be osmosis. Earlier work has been noted (E. S. R., 33, p. 68).

The effect upon appetite of the chemical constituents of the air of occupied rooms, C. E. A. WINSLOW and G. T. PALMER (*Proc. Soc. Expt. Biol. and Med.*, 12 (1915), No. 7, pp. 141-144).—The authors having noted in previous experiments carried out by the New York State Commission on Ventilation that vitiated air apparently caused a diminished appetite for food, this series of experiments was conducted. The subjects of the experiments (men and women) were placed in an observation room and on certain days were supplied with fresh air; on the other days no fresh air was supplied and the products of respiration were allowed to accumulate. Temperature and humidity were so regulated as to be the same on ventilation and nonventilation days. On each experimental day after the subjects had been in the chamber from 2 to 3 hours they were served a weighed luncheon of known calorific value and the amount of this eaten was determined.

From these experiments the conclusions were drawn that "there are substances present in the air of an unventilated, occupied room (even when its temperature and humidity are controlled) which in some way, and without producing conscious discomfort or detectable physiological symptoms, diminish the appetite for food. The effect of such an influence might in time be very important, and it seems possible that the observed beneficial effects of fresh air may to some extent be connected with this phenomenon."

On the respiratory exchange in fresh-water fish.—II, On brown trout, J. A. GARDNER and CONSTANCE LEETHAM (*Biochem. Jour.*, 8 (1914), No. 6, pp. 591-597, fig. 1).—In continuation of previous work (E. S. R., 32, p. 565), the apparatus employed is described, and data are reported regarding the amounts of oxygen necessary to maintain the life of the fish at different temperatures and under different pressures.

ANIMAL PRODUCTION.

The stockfeeder's companion, J. PORTER (*London: Gurney and Jackson, 1915, pp. XX+316, pls. 33, figs. 5*).—A general treatise on stock feeding and management, especially applicable to English conditions. Summaries of a large number of English experiments and feeding trials are included.

The international movement of feeding stuffs (*Internat. Inst. Agr. [Rome], Mo. Bul. Agr. Intel. and Plant Diseases*, 6 (1915), No. 4, pp. 481-516).—This

gives data on the production, consumption, and import and export trade in feeding stuffs of the various nations. An extensive bibliography is included.

Result of official chemists' analyses of feed stuffs (*Off. Bul. Ohio Agr. Coc., 6 (1915), No. 1, pp. 74-99*).—Analyses are given of alfalfa meal, middlings, tankage, cotton-seed meal, hominy feed, meat scrap, bran, gluten feed, linseed-oil meal, dried beet pulp, rye middlings, and various mixed and proprietary feeds.

Feeding stuffs, J. A. VOELCKER (*Jour. Roy. Agr. Soc. England, 75 (1914), pp. 274-276*).—Analyses are given of decorticated cotton cake, palm-nut cake and meal, and coconut cake.

The amino acid content of certain commercial feeding stuffs and other sources of protein, E. H. NOLLAU (*Jour. Biol. Chem., 21 (1915), No. 3, pp. 611-614*).—The distribution of the nitrogen of the amino acids of the following feeding stuffs is given: Soy beans, distillers' dried grains, cotton-seed meal, cowpeas, wheat bran, maize kernel, hemp seed, rice, sunflower seed, rolled oats, oat grain, sprouted oats, barley grain, rye grain, tankage, dried blood, peanuts, gluten flour, and gluten (wheat).

Among the individual peculiarities of the different mixed proteins may be mentioned "the absence of histidin in distillers' dried grains and in the cowpea; the absence of nonamino nitrogen, representing prolin and oxyprolin, in wheat bran and the maize kernel. The relatively large amount of lysin present in the soy bean, distillers' dried grains, wheat bran, dried blood, maize kernel, hemp seed, and sunflower seed is especially noteworthy. In contrast to this we have an absence of lysin in rice, oat grain, rolled oats, and barley grain. The monoamino acids constitute in most cases about one-half of the amino acids present. The high ammonia content and the low lysin content of gluten (wheat) and gluten flour is marked."

Concerning the distribution of cyanogen in grasses, especially in the genera *Panicularia* or *Glyceria* and *Tridens* or *Sieglingia*, C. L. ALSBERG and O. F. BLACK (*Jour. Biol. Chem., 21 (1915), No. 3, pp. 601-609*).—"Twenty-two species of American grasses were tested for cyanogen. Of these, cyanogen was found in *Tridens flavus*, *Panicularia nervata*, *P. grandis*, and *P. canadensis*. Three other American species of *Panicularia* examined, *P. pauciflora*, *P. fluitans*, and *P. septentrionalis*, did not contain it under the conditions of the examination. *Stipa vascyi*, sleepy grass of the Southwest, generally regarded to be poisonous, contained no cyanogen."

Bitter and sweet cassava, hydrocyanic acid contents, A. E. COLLENS (*Bul. Dept. Agr. Trinidad, 14 (1915), No. 2, pp. 54-56; abs. in Jour. Soc. Chem. Indus., 34 (1915), No. 11, p. 630*).—"The following percentage quantities of hydrocyanic acid were found in (A) sweet and (B) bitter cassava plants, the determinations being made immediately after the plants had been dug up: Leaves, (A) 0.0162, (B) 0.041; peel of stem, (A) 0.043, (B) 0.113; pith of stem, (A) 0.019, (B) 0.076; edible portion of root, (A) 0.0048, (B) 0.053. The hydrocyanic acid content of different parts of the freshly dug roots was the same, but after keeping for three days the upper part of the sweet roots contained about twice as much at the bottom portion; loss of water during air drying also caused the hydrocyanic acid content to increase. When sweet cassava was boiled with water for one hour, or roasted, no hydrocyanic acid was developed."

The composition and value of lupine seeds, G. MUENK (*Landw. Vers. Stat., 85 (1914), No. 6, pp. 393-416*).—The seeds of the blue, yellow, and white lupines are rich in ferments. In addition to a diastatic enzym and to others which split up glucosids and peptones and produce changes in urea, there is a ferment, heretofore overlooked, that forms lactic acid from amyllum and many kinds of

sugar and is of technical and toxicological importance. Possibly it might be used in the preparation of alcoholic beverages. There also exists in the seeds of the blue lupine a nonpoisonous agglutinating enzyme, a "phasin," as defined by Wienhaus and Kobert. On heating this enzyme to from 70 to 75° C., it is rapidly destroyed. The enzyme ricin, on the other hand, is not affected by this temperature, and this distinction between the two ferments serves as a useful test for detecting an admixture of castor oil seeds with blue lupine seeds. Further investigations are necessary to determine what kind of substance takes the place of phasin in the white and yellow lupines.

The influence of the composition and amount of the mineral content of the ration on growth and reproduction, E. V. McCOLLUM and MARGUERITE DAVIS (*Jour. Biol. Chem.*, 21 (1915), No. 3, pp. 615-643, figs. 11).—In these studies with rats, a ration was given the organic constituents of which were believed to be perfectly satisfactory for complete nutrition, but which was so low in mineral content that it would not suffice for growth at the normal rate. A mixture of a small amount of milk powder with purified sucrose, casein, butter fat, agar-agar, and dextrin was used. By lowering the content of milk powder, the only ingredient which carried appreciable amounts of bases, it was possible to regulate the base content of the diet at will. The rations ranged from an acidity of 14.31 cc. to an alkalinity of 102.09 cc. normal solution per 100 gm. In modifying the balance between the acid and basic radicals, additions of a salt mixture were employed.

Records of the growth and reproduction of the 20 groups of rats, and records of reproduction and certain details regarding the histories of the young were taken. A surprising uniformity of growth in all the animals of the various groups except the two receiving the highest additions of salts, which were stunted by the high salt content, was found. It was demonstrated that, provided the other factors in the ration are adequate, young rats can grow normally and remain in apparent good health on rations whose base content varies widely in amount.

Confirming the results of previous experiments, in which egg yolk as a restricted diet was found not to be deleterious as the result of its acid character, four of the rations employed in this work were highly acid, yet growth and well-being were not markedly interfered with. It was further found that growth to the normal adult size at the usual rate and a continued well-nourished appearance are not sufficient evidence that a ration is fully adequate. Only when normal reproduction and rearing of the young is repeated at normal intervals can a ration be said to be physiologically sufficient.

The improvement in the growth of rats noted as the result of adding suitable salt mixtures to rations restricted to corn or wheat kernel, or to other rations made up of purified food substances, is attributed to the fact that there is a correction of the mineral content of the ration. On the other hand, the addition of salts alone to a ration derived entirely from wheat or wheat and wheat gluten gives a diet which is a wonderful improvement over the grain alone, yet such rations give less than half normal growth and do not suffice for prolonged maintenance.

The query is made whether there is an interdependence between an unfavorable mineral content and other factors in the diet which causes the inorganic deficiencies to be more pronounced in some cases than in others. See also previous notes (E. S. R., 26, p. 467; 29, p. 64).

[Animal husbandry work in Alaska], C. C. GEORGESON ET AL. (*Alaska Stas. Rpt. 1914*, pp. 32-34, 40-42, 74, 75, 76-77).—It is noted that two dairy herds are being kept near Fairbanks. The cows are kept warm and comfortable in winter, while in summer they run at pasture for about three or four months.

There are no herds of beef cattle in the interior, owing to the cold winters, and the beef consumed consists almost wholly of cold-storage meat brought from the outside. It is thought that a hardy beef animal for the interior can be developed by making reciprocal crosses between the yak and the Galloway. While it is true that some of the hybrids are not fertile, there are others that are fertile, especially when the bull is crossed on the female yak. A letter from V. Pisareff, director of the experiment station in the Government of Irkutsk, Siberia, is given in which it is said that the yak is frequently crossed on common cattle in Mongolia, that both the yak and his hybrid offspring are exceedingly hardy, that they obtain their feed through the long and extremely cold winter practically without the aid of the owners, and that they are much used for beef and for milk, as well as for work animals. It is suggested that an experiment of this nature be conducted at the Fairbanks Station.

At the Kodiak Station the herd has been reduced, the animals retained being mostly those proved to have some milking qualities. It is said that the Alaska settler needs milk quite as much as beef, and inquiries from prospective buyers are mostly for family cows. The destruction of the greater part of the sheep flock by brown bears at Kodiak Station is reported. It is stated that so long as the brown bear is protected by law there can be little encouragement for the live-stock industry. Galloway cattle at this station are doing well. The cattle are maintained on feed natural to the country, along with what can be grown by cultivation. Experiments are being made with all kinds of promising fodder crops that can be grown in this country for winter feed for live stock.

A contribution to our knowledge of the chemistry of coat color in animals and of dominant and recessive whiteness, H. ONSLOW (*Proc. Roy. Soc. [London], Ser. B, 89 (1915), No. B 609, pp. 36-58*).—The author concludes from his studies that “the existence of a tyrosinase in the skins of vertebrates is inconclusive. A peroxidase can, however, be extracted from the skins of certain colored rabbits and mice, which behaves like a tyrosinase toward tyrosin in the presence of hydrogen peroxid. It can be precipitated from solution by saturation with ammonium sulphate or by an excess of alcohol. The peroxidase present in agouti, chocolate, and blue rabbits is indistinguishable in its reactions from that present in black rabbits; but no peroxidase could be extracted from yellow and orange rabbits.

“‘White melanin’ is not a pigment substance, nor is it the cause of dominant whiteness, which is due to the presence of an inhibitor or antityrosinase in the skin. Dominant whiteness in the English rabbit is due to the presence of a tyrosinase inhibitor in the skin, which destroys the activity of tyrosinase; and the dominant white bellies of yellow and agouti rabbits are due to the same cause. The inhibitor can be precipitated by saturation with ammonium sulphate, and is destroyed by boiling or by standing for 48 hours. Recessive whiteness in rabbits and mice is due to the lack of the enzym unit of the pigment-producing system, for no tyrosinase or antityrosinase could be extracted from their skins.

“There is not sufficient evidence to decide whether a chromogen is present or not. The presence of an unoxidized chromogen might, however, serve to explain the occurrence of certain colorless granular particles which are found in the medullary cells of the hairs of some white animals. These particles are microscopically visible when stained, and in appearance very closely resemble colored pigment granules.

“The capacity of both white and colored skin extracts to oxidize dihydroxyphenols, but not monophenols, is more probably due to the catalyzing effect

of organic colloidal material than to a true enzym. The extreme resistance to high temperatures shown by these extracts excludes the presence of an enzym as generally understood. Variations in coat color are due probably to a quantitative rather than to a qualitative difference in the pigment present, for the pigments isolated from black, chocolate, and yellow rabbits show very little difference either in the depth of their color or in their chemical behavior. Blue and the other dilute coat colors are not caused by a lack of pigment in the medulla, but by the absence of granules in the cortex, which, being present in the intense colors, absorb the light which in the dilute colors is reflected from the vacuoles."

Note on a case of Hunter's freemartin, where there was reversion to the wild park cattle type, D. B. HART (*Edinb. Med. Jour., n. ser., 14 (1915), No. 3, pp. 194-198, pl. 1; abs. in Jour. Roy. Micros. Soc., No. 3 (1915), p. 238*).—A freemartin is described "which resembled the wild park cattle in having a white hide, black muzzle, black hoofs, blackish spots on the legs, and great timidity. The mother was a normal Shorthorn; the cotwin a normal bull. A typical Hunter's freemartin is a sterile, genitally malformed bull, with small undescended testes and rudimentary epididymes, vasa deferentia, and Müllerian elements. Vesiculæ seminales are present. The external genitals consist of labia majora, clitoris, and the urinogenital sinus element (one in. in length) of the vagina.

"The potent bull calf and the freemartin are produced from one fertilized ovum, but the freemartin has allotted to it the hydatid testis and prostatic utricle normally given to the single bull. This produces an exaggerated simulacrum of the female genital tract.

"The thyroid, thymus, and suprarenals were found to be normal. The internal genitalia showed fatty degeneration, and were represented only by the urinogenital sinus and the epididymes. The skull was normal. The chief point of interest was the (ectodermic) reversion to the wild park cattle type. A theoretical interpretation is given of the way in which this reversion might come about—by retention of certain ancestral chromosomes normally lost in polar body formation."

German breeds of live stock (*Arb. Deut. Landw. Gesell., No. 235 (1912), English ed., pp. 93, pls. 53, figs. 12*).—Descriptions of the principal breeds of horses, cattle, sheep, and swine of Germany are given. The book is profusely illustrated with photographs of the prize-winning animals of each breed.

The value of German breeding cattle in German Southwest Africa, J. NEUMANN (*Abhandl. Hamburg. Kolon. Inst. 26 (1914), Ser. E, pp. 35, pls. 16*).—An account of the distribution of the various breeds of cattle in German Southwest Africa, together with measurements of representative animals of each breed.

Lincolnshire Red Shorthorns, G. E. COLLINS (*Jour. Roy. Agr. Soc. England, 75 (1914), pp. 33-40, pl. 1*).—An account of the early history, development, and utility value of the Lincoln Red breed of cattle.

Profits in southern cattle feeding, R. S. CURTIS (*Breeders' Gaz., 67 (1915), No. 10, p. 510*).—In order to obtain data on the beef cattle feeding industry members of the North Carolina Beef Breeders' and Feeders' Association purchased cooperatively, in 1914, 730 feeding cattle weighing from 900 to 1,100 lbs. from the western or mountainous portion of the State. These cattle were shipped to various farms throughout the State, where they were fed under ordinary farm conditions, the feeder placing his own valuation on the feed, bedding, manure, and other incidentals.

The gain of the average steer was 1.03 lbs. per day for the 121-day feeding period. The tons of manure per steer totaled 3.98, valued at \$2.44 per ton. The average profit per steer, including the value of the manure, was \$6.99.

These results are not taken as conclusive but merely as indicative of the average profit which may be expected from the industry.

Data on sex determination in cattle, R. PEARL and H. M. PARSHLEY (*Biol. Bul. Mar. Biol. Lab. Woods Hole, 24 (1913), No. 4, pp. 205-225*).—In this paper statistics collected some years ago (E. S. R., 4, p. 359) at the Maine Experiment Station in regard to the relation between time of service in the oestrous period and the sex of the subsequent offspring in domestic cattle are subjected to biometric analysis. It is stated that these statistics are much more extensive than any which have hitherto been collected for the study of this problem in cattle.

It is shown "that as the time of coitus approaches the end of the oestrous period there is a progressive increase in the proportion of male young born. In the extreme case this increase in the proportion of male births is probably statistically significant and not to be attributed to errors of random sampling. These modifications of the sex ratio can not be attributed to age differences or to any other factor yet suggested." It is thought that possibly "the observed changes in the sex ratios are correlated with changes in the relative freshness (or staleness) of the ova at the time of fertilization."

The facts set forth in this paper warrant the breeder in paying attention to the time of service in his cattle breeding operations, but he must not suppose that by so doing he can absolutely control the sex of the offspring, or even approach measurably close to absolute control. He can at best merely modify, over a period of years, the sex ratio in greater or less degree, in the direction which he desires.

Study of the form and weight of young cattle, K. INDERMÜHLE (*Jahresber. Landw. Schule Rütli, 1912-1914, pp. 129, 130*).—The average weight and body measurements of cattle from six months to three years of age are given.

The rearing of calves on substitutes for milk fat and milk, B. N. WALE (*Jour. Brit. Dairy Farmers' Assoc., 29 (1915), pp. 110-119, pl. 1*).—A résumé of English and American experiments along this line.

Blackface sheep, R. M'MILLAN (*Trans. Highland and Agr. Soc. Scot., 5. ser., 27 (1915), pp. 142-158, figs. 8*).—An account of the development and characteristics of this breed of sheep.

Border Leicester sheep, J. R. C. SMITH (*Trans. Highland and Agr. Soc. Scot., 5. ser., 27 (1915), pp. 159-167, figs. 5*).—An account of the development and characteristics of this breed of sheep.

"Blanket" system of handling sheep on the Madison National Forest, C. E. FLEMING (*Nat. Wool Grower, 5 (1915), No. 5, pp. 7-10, figs. 2*).—In an experiment conducted by the Forest Service of the U. S. Department of Agriculture it was found that the sheep which were run under the old system of close herding and returning to a permanent camp ground each night used 47 per cent more range than the sheep that were allowed to graze quietly and openly and bedded where night overtook them, except when it was clearly impracticable to move the camp due to rainy weather or heavy fogs. The average gain per day of the lambs under the new system was 0.43 lb. compared with 0.38 lb. made under the old system. It is estimated that each lamb grazed under the blanket system made a gain of 22½ cts. per head more for a period of 90 days than the lambs grazed under the old method.

It is stated that any of the standard breeds of sheep adapted to western conditions may be economically handled under this new system. The fine-wooled

sheep are much more easily herded than either the medium-wooled or coarse-wooled breeds. By the use of a cross between the Rambouillet, or one of the members of the fine-wooled breeds, with the Hampshire, Shropshire, Lincoln, or Cotswold, the weight and fineness of the fleece can be increased, the size of the carcass maintained, and the herding qualities improved. The blanket system is especially adapted to the production of an early maturing lamb.

Possibility of producing more and better sheep by improvement in methods of handling on the range, J. T. JARDINE (*Nat. Wool Grower*, 5 (1915), No. 4, pp. 15-18, figs. 2).—Another description and account of "bedding out" or "blanketing" experiments with sheep on the range, as reported above.

The "bedding out" system of handling sheep on Big Horn Forest, Wyoming, L. H. DOUGLAS (*Nat. Wool Grower*, 5 (1915), No. 6, pp. 13-16, figs. 2).—The results of the experiments here reported confirms those noted above.

Handling sheep on timber and brush ranges of Idaho, B. S. MARTINEAU (*Nat. Wool Grower*, 5 (1915), No. 7, pp. 7-11, figs. 2).—The "bedding out" method of handling sheep on the timber and brush ranges of Idaho proved to be satisfactory and in line with the results secured on other ranges (see above).

The properties of wool, W. DAVIS (*Trans. Highland and Agr. Soc. Scot.*, 5, ser., 27 (1915), pp. 168-191, figs. 9).—The subjects discussed in this article are requirements of "handle," wool varieties in a fleece, classing of fleeces, structure of the fiber, color, disposition of fiber, the Cheviot fleece, the Southdown fleece, the Blackface fleece, felting property, influence of crossing on the wool structure, abnormal fibers, moisture in wool, and utility of the hygroscopic quality.

Dried chicory roots as horse feed, A. W. DONEGAN (*U. S. Dept. Com., Com. Rpts.*, No. 156 (1915), pp. 74, 75).—It is reported that chicory roots make an excellent substitute for oats, containing moisture 13.79, protein 4.85, fat 0.85, and nitrogen-free extract 69.73 per cent, with 4.35 per cent of sugar. There are estimated to be about 57 feed units as compared with 82 feed units in dried sugar beets.

No digestive troubles have been noticed in feeding the chicory; in fact it is thought to have a favorable influence on the digestion. The material is readily consumed by horses in quantities up to 10 lbs. daily per horse. It is thought that if the material could be ground up and sugar or molasses mixed in, an ideal feed could be made.

Alfalfa hay for hogs, L. FOSTER and H. H. SIMPSON (*New Mexico Sta. Bul.* 96 (1915), pp. 32, figs. 3).—Supplementing previous work (E. S. R., 31, p. 470), two lots of three 125-lb. Tamworth barrows each were fed 63 days in winter as follows: Lot 1, 4.7 lbs. of grain (shelled corn and Kafir corn) per head daily, and lot 2, 6.9 lbs. of grain, both lots receiving what alfalfa hay they would consume. The respective lots made average daily gains of 1.13 and 1.61 lbs. per head, consuming 4.14 lbs. of grain and 0.92 lb. of alfalfa and 4.28 lbs. of grain and 0.554 lb. alfalfa per pound of gain, and costing 6.83 and 6.85 cts. per pound of gain.

The results of this experiment indicate that about 15 per cent more profit can be made by feeding a heavy grain ration, at least 2 lbs. per 100 lbs. live weight, with alfalfa hay than by feeding a medium grain ration. The largest returns per ton for the alfalfa, after paying for the grain consumed, were made by lot 2. However, the small amount of roughage that the hog will economically use when being fattened makes this a secondary consideration. The desirability of the bacon breeds of hogs for New Mexico conditions is noted.

Four lots of three or four 8-months-old Duroc-Jersey and Tamworth pigs each were fed 135 days as follows: Lot 1, skim milk and alfalfa hay; lot 2, skim milk, a grain mixture of shorts and bran, and alfalfa hay; lot 3, shelled corn and alfalfa hay; and lot 4, skim milk, ground corn, and alfalfa hay.

The alfalfa hay was fed in racks, and just as much as they would clean up without waste. The amount of skim milk and grain fed was regulated by the size of the pigs, and increased as the pigs gained. It was considered that 6 lbs. of skim milk was equal to 1 lb. of grain as a feed, and that the most economical proportion to feed it in conjunction with grain was 4 : 1.

The respective lots made average daily gains per head of 0.33, 0.43, 0.54, and 0.54 lb., consuming per pound of gain 3.92, 3.99, 3.52, and 3.32 lbs. of grain or equivalent, and costing 9.35, 8, 6.49, and 6.83 cts per pound of gain. The results of the experiment indicate that when skim milk is fed with alfalfa hay it should be supplemented with one of the concentrated carbohydrate grains, such as corn, barley, or milo maize, rather than with either a concentrated nitrogenous or a bulky grain.

It was noted that the Duroc-Jersey pigs gained more than the Tamworths on all feeds except shelled corn and alfalfa. Considering the two breeds regardless of the rations fed, the Durocs made an average gain of 66 lbs. per head and the Tamworths 60 lbs.

Four lots of eight 8-month-old Duroc-Jersey and Tamworth pigs each were fed 90 days as follows: Lot 1, soaked barley and alfalfa hay; lot 2, soaked wheat and alfalfa hay; lot 3, ground wheat, wet with water, and alfalfa hay; and lot 4, ground wheat and skim milk 1 : 4, and alfalfa hay. The respective lots made average daily gains per head of 0.718, 0.8, 0.958, and 0.899 lb., consuming 4.48, 4.02, 3.35, and 2.61 lbs. of grain and 0.99, 0.66, 0.98, and 1.17 lbs. of alfalfa hay per pound of gain, costing 6.82, 4.99, 4.63, and 5.29 cts. per pound of gain, and returning a profit of \$0.856, \$2.215, \$2.865, and \$2.205 per head. The Durocs in every lot but one (lot 4) made the larger gains, but the Tamworths seemed better able to utilize the bulky skim milk plus wheat ration. Both breeds gained more on wet ground wheat than on soaked, and the Tamworths seemed to relish it more than did the Durocs.

Four lots of eight pigs each were fed 36 days as follows: Lot 1, ground barley and silage; lot 2, ground barley and shorts, 2 : 1, and silage; lot 3, ground barley and alfalfa hay; lot 4, ground barley and shorts, 2 : 1, and alfalfa hay. The respective lots made average daily gains per head of 0.48, 0.5, 0.68, and 0.7 lb., lots 1 and 2 consuming 10.33 and 9.8 lbs. of silage and 6.7 and 6.04 lbs. of grain per pound of gain and lots 3 and 4 consuming 4.72 and 4.27 lbs. of alfalfa hay and 4.7 and 4.45 lbs. of grain per pound of gain, and costing, respectively, 12.94, 11.74, 10.36, and 9.7 cts. per pound of gain.

As between silage and alfalfa the average total gain per head was 17.6 lbs. and 24.8 lbs., the average cost per pound of gain 12.34 and 10.02 cts., and the average profit by carload \$9.55 and \$38.37. As between the barley and the barley and shorts rations the average total gain per head was 20.7 and 21.6 lbs., the average cost per pound of gain 11.65 and 10.72 cts., and the average profit per carload \$15.43 and \$32.67.

It is estimated that 585 lbs. of alfalfa hay replaced 500 lbs. of concentrate of the kinds used in these experiments, and that the hay has a value of \$25.64 per ton.

Ground corn gave better results than skim milk supplemented with shorts and bran or skim milk supplemented with ground corn, though when a portion of the ground corn was replaced by skim milk the gains were as high but made at a greater cost.

Taking the average results of three experiments in which Tamworths were used, including 26 hogs, and comparing with the results of two experiments in which Duroc-Jerseys were used, including 27 hogs, the average daily gain of the Tamworths per head was 31 per cent greater than that of the Duroc-Jerseys,

but it required 3.5 per cent more feed to make 100 lbs. of gain with Tamworths than with Duroc-Jerseys. In prolificacy both breeds stood high, the Tamworths averaging in 15 litters 3.8 pigs to the litter and the Duroc-Jerseys in 21 litters 9.1 pigs per litter.

The general average of the several lots of the four experiments shows that alfalfa hay constituted 31.9 per cent of the feed eaten. The quantity ranged from 11.4 per cent with a heavy concentrate ration to 51 per cent with a ration of skim milk. In general, the percentage was high with a light or medium concentrate ration and lower with the heavier concentrate rations.

The use of the paunch contents of freshly slaughtered cattle as a pig feed (*Deut. Landw. Presse*, 42 (1915), No. 12, pp. 90, 91).—The paunch contents of freshly slaughtered animals is being used as a pig feed in Germany, 100 lbs. of this material being mixed with 10 liters of blood, 20 lbs. of molasses peat meal, 3½ lbs. of salt, and a little whiting. This has about one-fourth the feeding value of an equal quantity of potatoes.

The Large White Yorkshire pig, S. HEATON (*Jour. Roy. Agr. Soc. England*, 75 (1914), pp. 40-50, pl. 1, fig. 1).—A discussion of the breeding, feeding, care, and management of the Large White Yorkshire breed of hogs.

Poultry, A. F. ROLF and L. F. PAYNE (*Oklahoma Sta. Bul.* 106 (1914), pp. 31, pl. 1, figs. 8).—Part 1 of this bulletin deals with breeds and breeding, poultry diseases, and farm poultry housing. Part 2 discusses incubation, brooding, and feeding.

Telling the sex of day-old chicks, W. F. FRY (*Rel. Poultry Jour.*, 22 (1915), No. 5, pp. 593-595, 629, figs. 4).—It is said that the sex of day-old Barred Plymouth Rock chicks can be determined without difficulty. The male characteristics are the coarser appearance of the chick's head, the greater admixture of white with black in the plumage, which gives a lighter-gray effect, and the clear yellow color of leg and beak. The female characteristics are a neater head, stronger-black coloring, and dark beak and legs.

Third annual international egg-laying contest, W. F. KIRKPATRICK and L. E. CARD (*Connecticut Storrs Sta. Bul.* 82 (1915), pp. 57-99, figs. 21).—In experimental pens in connection with this contest it was demonstrated that milk may be substituted for green feed or for meat but not for both when the regular contest ration was fed. Birds supplied with a prepared feed for which they did not have to scratch did not do so well as those receiving the ordinary contest ration.

It was found that the weight of eggs from the different breeds varied considerably. The Leghorn eggs averaged about 1.5 lbs. to the dozen, the Wyandotte eggs 1.483 lbs., the Plymouth Rock eggs 1.588 lbs., and the Rhode Island Reds 1.602 lbs. The average for all breeds was 1.537 lbs.

The highest percentage of broody birds was found in the Rhode Island Reds and the lowest in the Leghorns, the average number of days lost for all breeds being 20.9 days per hen per year, while each broody hen lost 56 days. The average for the heavy breeds was 34.3 days.

At the close of the contest the Leghorns averaged in weight 3.51 lbs. per bird, the Wyandottes and Rhode Island Reds 5.45 and 5.59 lbs., and the Plymouth Rocks 5.94 lbs. The Plymouth Rocks, Wyandottes, Rhode Island Reds, and the miscellaneous group all reached their highest production in the month of April, while for the Leghorns May was the best month. The cost of feed to produce a dozen of eggs was in the case of the Plymouth Rocks 16.1 cts., the Wyandottes 14.3 cts., the Rhode Island Reds 15.8 cts, and the Leghorns 12.4 cts.

Yield data, etc., are also included.

Report on the fourth egg-laying competition at Burnley, 1914-15, A. HART (*Jour. Dept. Agr. Victoria*, 13 (1915), No. 6, pp. 321-339, figs. 13).—In this competition six White Leghorn hens on dry mash feed laid during the 12-month period 1,699 eggs, six Black Orpingtons on wet mash feed 1,562 eggs, six White Leghorns on wet mash feed during a 4-month winter test of the light breeds 565 eggs, and six Black Orpingtons on a wet mash feed during a 4-month winter test of the heavy breeds 502 eggs. These are said to be world records.

Parafield egg-laying competition, D. F. LAURIE (*Jour. Dept. Agr. So. Aust.*, 18 (1915), Nos. 9, pp. 741-747; 10, pp. 870-888; *Dept. Agr. So. Aust. Bul.* 93 (1915), pp. 23).—A report of the Parafield egg-laying competitions of 1914-15.

Control of the marketing of eggs, A. BEHRE and K. FRERICHS (*Ztschr. Untersuch. Nahr. u. Genussmit.*, 27 (1914), No. 1-3, pp. 38-59).—In these studies it was found that the specific weight of absolutely fresh eggs varied between 1.068 and 1.1, while general market eggs varied between 1.073 and 1.094, only 6 per cent being above that and 5 per cent below these figures. The absolute weight of the eggs ranged from 44.5 to 69.5 gm. apiece, but there appeared to be no relation between absolute and specific weights. Under storage there was a decrease in absolute weight of from 0.054 to 0.167 gm., with an average of 0.086 gm., per day, and a decrease in specific weight of from 0.001 to 0.0034, with an average of 0.0017, per day.

DAIRY FARMING—DAIRYING.

Report of the progress made in the field of milk chemistry and dairying during the year 1913, W. GRIMMER (*Milchz. Zentbl.*, 43 (1914), Nos. 19, pp. 481-486; 20, pp. 497-503; 21, pp. 513-517; 22, pp. 530-535; 23, pp. 551-556; 24, pp. 569-572; 44 (1915), Nos. 1, pp. 3-8; 2, pp. 17-23; 3, pp. 33-40).—The subject is dealt with under the following headings: Keeping of animals and milk production; various kinds of milk; milk constituents; changes in milk and its constituents; bacteria; enzymes; immune bodies; milk as antigen; rennet and rennet coagulation; milk as food; dairy products; dairy apparatus; milk distribution; and investigational methods.

The practicability of starch values in dairy cattle feeding, B. SJOLLEMA (*Jour. Landw.*, 62 (1914), No. 4, pp. 345-375).—The author concludes that Kellner's starch values are not a safe measure in the feeding of dairy cows. The quantity of protein necessary to produce the unit of milk (10 kg.) can not be exactly determined; it is, however, not far from 0.4 kg., assuming that out of 100 parts of digestible protein in the ration 88 parts are transformed into milk protein. For the formation of milk sugar probably 0.5 kg. of carbohydrates is necessary for 10 kg. of milk, assuming that 90 parts out of 100 are converted into sugar. In practice, taking into account individual differences, etc., it will be better to feed a little more protein and carbohydrates, that is, from 0.45 to 0.6 kg., respectively. The milk fat will be formed, as a rule, partly from the fat and partly from the carbohydrates of the food.

In establishing the rations of milch cows which have reached full growth the author considers that provisionally the following quantities may be accepted, taking into account individual conditions: Three-tenths kg. of protein and 3 kg. of starch value for the maintenance ration per 500 kg. live weight; 0.45 kg. of protein for the formation of the protein for 10 kg. of milk; and 0.6 kg. of carbohydrates for the formation of the milk sugar in 10 kg. of milk. Besides these, there are the carbohydrates and fats required for the production of milk fat.

Feeding experiments with dairy cows, A. FLÜCKIGER and K. INDERMÜHLE (*Jahresber. Landw. Schule Rütli, 1912-1914, pp. 105-117*).—In experiments to determine the amount of grain to feed cows yielding various amounts of milk it was concluded that cows giving 15 kg. of milk daily should receive 2 kg. of grain mixture per head per day; cows giving 12 kg. of milk, 1.5 kg. of grain; and cows giving 10 kg. of milk, 1 kg. of grain. Cows giving more than 15 kg. of milk demand a correspondingly richer feed.

The effect of palm-oil cakes upon milk production in cows, J. HANSEN (*Landw. Jahrb., 47 (1914), No. 1, pp. 1-70*).—The author concludes from a critical review of the experiments made by other workers and from the results of his own experiments that palm-oil cake does not affect the milk yield, but increases its fat content. This specific action increases with the increase of the amount of cake in the ration and with the quantity of fat in the palm-oil cake itself. In order to obtain a perceptible specific effect, at least from 2.5 to 3 lbs. per 1,000 lbs. of live weight should be used if the cake is somewhat deficient in fats, or 2 lbs. per 1,000 lbs. live weight if it is rich in fats.

The effect of the palm-oil cake varies with the individual cows, but is in every case perceptible when the cake is fed in sufficient quantities. Neither the milk yield nor the period of lactation, when the palm-oil cake is introduced into the rations, seems to have any influence upon its action. It is thought that an increase of from 0 to 0.14 per cent in the fat content of the milk is small; from 0.14 to 0.2 per cent, average; and above 0.2 per cent, large.

The influence of sugar beet feeding on the composition of the milk fats, J. BOES and H. WEYLAND (*Ztschr. Untersuch. Nahr. u. Genussmitl., 29 (1915), No. 12, pp. 473-475*).—A résumé of investigations on this subject. In general there is an increase in the Reichert-Meissl, Polenske, and saponification numbers, a lowering of the ash content, and an increase in the volatile soluble and insoluble fatty acids of the milk fat with the feeding of sugar beets to cows.

Grass palatability tests, E. BREAKWELL (*Agr. Gaz. N. S. Wales, 26 (1915), No. 6, pp. 485, 486*).—In feeding trials with Jersey cows, in which records were kept of the time taken to consume a given amount of the different grasses, it was found that prairie, Paspalum, and Hungarian brome grasses were easily the most palatable species in the young stages, and Paspalum and Hungarian brome grass in the seeding stages. Contrary to expectations, the Paspalum was eaten very readily, even in its mature stages. In both cases Rhodes grass was only eaten on compulsion. The native grasses were disregarded in favor of the cultivated. This happened at both stages of growth.

The results of the experiments are deemed only suggestive, as it is thought that several factors, such as the chemical and physical texture of the soils, climatic conditions, and individual variation among the animals, must be taken into account as affecting the palatability of grasses.

The reaction and calcium content of milk as factors in the coagulation process, T. H. MILROY (*Biochem. Jour., 9 (1915), No. 2, pp. 215-228*).—The author concludes from his studies that "during the course of rennin action there is no change in the hydrogen ion concentration of milk, either in the earlier stage or in the actual separation of the clot. The addition of an alkaline oxalate to milk lowers, while that of CaCl_2 raises, the hydrogen ion concentration. Fresh milk which has been subjected to a temperature slightly below boiling point for one hour shows a rise in the hydrogen ion concentration, and a fall in the calcium content. Such milk is only very slowly acted upon by rennin.

"The coagulability of heated milk may be raised either by the addition of CaCl_2 or by raising the hydrogen ion concentration. The former does not

act simply by raising the hydrogen ion concentration nor the latter from its effect upon the soluble calcium content. The acid precipitation zone of caseinogen lies on the acid side of the rennin zone of action, but the latter gradually approaches the former as the calcium content of the mixture is lowered, so that in all probability the latter is an extension of the former toward the neutral point. Calcium chlorid, apart from its effect upon the hydrogen ion concentration, increases the activity of the rennin ferment from the beginning of the digestion process."

Relation of numbers of *Streptococcus lacticus* to amount of acid formed in milk and cream, P. G. HEINEMANN (*Abs. in Science, n. ser.*, 42 (1915), No. 1079, p. 321).—Flasks of both sterilized and raw milk and cream inoculated with *S. lacticus* were incubated at temperatures of 37, 20, and 7° C. and the bacteriological results compared with flasks left to sour spontaneously.

It was found that "the amount of acid formed during the souring process of milk or cream is not solely dependent upon the number of bacteria present of the *S. lacticus* group. Temperature and the presence of other bacteria may influence the result. In raw milk or cream or in raw milk or cream inoculated with cultures of *S. lacticus* the number of bacteria increases to a given point and then decreases. The higher the temperature up to 37° the earlier is the maximum number reached. Coagulation of milk or cream is not dependent solely upon a certain amount of acid or a certain number of bacteria. After the decline in numbers the amount of acid continues to increase, probably due to enzym action. At 37° extraordinarily large amounts of acid may be formed, due probably to the presence of members of the group of lactobacilli."

The alkali-forming bacteria found in milk, S. H. AYERS and P. RUPP (*Abs. in Science, n. ser.*, 42 (1915), No. 1079, pp. 318, 319).—A brief account.

The preservation of milk by freezing, G. FASCETTI (*Staz. Sper. Agr. Ital.*, 48 (1915), No. 1, pp. 61-65).—A discussion of the effect of freezing upon the physical characteristics of milk.

The refrigeration of a city's milk supply, C. BATES (*Abs. in Science, n. ser.*, 42 (1915), No. 1079, p. 319).—In bacteriological examinations of a city's milk supply the Bureau of Chemistry of this Department has found that the chief cause of high bacteriological counts was due to nonrefrigeration of milk in transit, the average temperature of the milk upon receipt in the city being about 65° F. This milk was en route from 6 to 12 hours. Refrigeration has now been provided by the railroads, and the milk at the present time is being received in the city at about 48°.

Factors influencing the resistance of lactic acid bacteria to pasteurization, K. PEISER (*Abs. in Science, n. ser.*, 42 (1915), No. 1079, p. 320).—In milk and cream pasteurized at 63° C. were found a number of strains of the *Bacterium lactis acidi* type, whose thermal death point in broth is below the pasteurization temperature. The average thermal death point is in whole milk 5°, in separated milk 2.5°, and in whey 0.5° higher than in bouillon. These results indicate that the protection given to the suspended lactic bacteria by the casein and coagulated albumin of separated milk raises their thermal death point 2.5° and that the protein and fat of whole milk raises their thermal death point 5°.

Silicic acid in milk from sterilization in glass bottles, B. PFYL (*Molk. Ztg. Berlin*, 25 (1915), No. 23, pp. 177, 178).—Ordinarily there is from 0.8 to 1.1 mg. of silicic acid (SiO₂) per 500 cc. of milk. When milk is sterilized in glass bottles there is an increase of from 0 to 0.7 mg., depending upon the condition of the bottles.

[Waste in milk delivery] (*U. S. Dept. Agr., Weekly News Letter*, 2 (1915), No. 51, pp. 1, 2).—From data collected by the Dairy Division of this Department

It was found that in the District of Columbia the shortest distance traveled by any wagon was 10.4 miles per day and the longest was 30, the average distance being 19.1 miles. The total distance covered by all the wagons was 93 times the entire distance of all the streets in the District. Data from three other cities are given bearing out the same results.

While much of the waste in milk deliveries can not be prevented, because there are so many dealers in each locality, it is suggested that efforts should be made by the dealers to concentrate their business as much as possible so as to lessen the distance traveled by the wagon for each quart of milk delivered. They should try to secure a large number of customers in a small area.

Using the Babcock test, J. M. FULLER (*Oklahoma Sta. Bul. 107 (1915), pp. 3-15, figs. 16*).—General instructions are given.

VETERINARY MEDICINE.

Department of veterinary science and bacteriology, W. B. MACK (*Nevada Sta. Rpt. 1914, pp. 21-24*).—A brief statement of the work of the year with equine anemia, hog cholera, chicken cholera, and umbilical necrobacillosis.

The use of suspensions of the dead virus during an outbreak of chicken cholera in a flock of more than 300, of which 170 were treated, apparently gave successful results, since the loss promptly ceased. An outbreak of umbilical necrobacillosis during the lambing season in a large flock resulted in the death of 1,540, or about 70 per cent of the total number. It is stated that the results obtained in the use of antihog-cholera serum have been uniformly successful and every outbreak promptly suppressed with insignificant losses. But slight progress has been made in the work with equine anemia owing to the number of cases being few.

The detection of anthrax bacilli in the bone marrow, K. GRABERT (*Ztschr. Infektionskrank. u. Hyg. Haustiere, 16 (1915), No. 5, pp. 324-336*).—The Foth azure dye-staining method gave good results. The procedure, aside from the long time required for its execution, is simple to conduct and it can be carried out where the autopsy is conducted. The cultural test was found less reliable. Fifty-two animals, chiefly bovines, were under examination. The bones best suited for taking the marrow samples are named.

Foot-and-mouth disease in Denmark, J. J. DUNNE (*Hoard's Dairyman, 50 (1915), No. 7, p. 190*).—The author here quotes an interview had with Dr. B. Bang in August, 1915, concerning the recent outbreak of foot-and-mouth disease in Danish dairy herds.

It is stated that from November, 1914, up to August 5, 1915, the disease has been detected in no less than 5,734 herds, with a total of 200,000 cows and 130,000 pigs.

"Cows suffering from the disease go back in their milk to such an extent as to entail a loss of \$5 to \$7.50 for each animal. If we take \$6.25 as the average, the loss of milk alone amounts to \$1,250,000. In addition to this the mortality in 1911-12 constituted $\frac{1}{2}$ per cent for adult animals; $\frac{3}{4}$ per cent for young stock; and over 23 per cent for calves. In 1914-15 the percentages all round were higher; 37 adult animals died at Koselitz and 100 at Brattingsborg on the island of Samso. Nearly all the young hogs and many adult hogs attacked by the disease died also.

"The only things that help are care, caution, isolation, and regular disinfection. Laxity in regard to those things will entail still larger losses than those already sustained."

Studies on the biochemistry and chemotherapy of tuberculosis.—X, An experimental study of the influence of iodine and iodides on the absorption of granulation tissue and fat-free tubercle bacilli, E. F. HIRSCH (*Jour. Infect. Diseases*, 15 (1914), No. 3, pp. 487-500).—“The use of iodine and iodides in facilitating the absorption of necrotic material and organization of tuberculous and other granulation tissues has no experimental proof. The daily administration of potassium iodide does not hasten the removal of foreign substances, like tubercle bacilli, by stimulating the phagocytic properties of the endothelial cells. The presence of free iodine in such areas may influence the process only by favoring an inflammatory reaction, if the amount of iodine is sufficient, but has no effect in promoting absorption. Iodized fat-free tubercle bacilli are absorbed no faster than are the noniodized.”

Studies on the biochemistry and chemotherapy of tuberculosis.—XI, The therapeutic value of copper and its distribution in the tuberculous organism, H. J. CORFER (*Jour. Infect. Diseases*, 15 (1914), No. 3, pp. 518-540).—“Copper, in simple salt form (sulphate, acetate, oleate, and copper amino-acid mixture prepared from hydrolyzed egg albumin), injected intramuscularly into normal and tuberculous guinea pigs, in total amounts from 0.75 mg. up to about 19 mg. for about 2 to 100 days, enters the animal organism and is found mainly and in largest amounts in the liver, in small amounts in the kidneys, in traces in the spleen, lungs, and blood, and not at all in the tuberculous lymph glands and pus. After cessation of injections the copper slowly but gradually decreases in amount in the liver.

“Copper, in simple salt form, injected intramuscularly in guinea pigs in amounts varying from 2.7 to 22.1 mg. during a period of 13 to 34 days, previous to (19 days), coincident with (2 days before), or after (11 days) infection with tubercle bacilli, has no appreciable effect upon the progress of the tuberculosis, as indicated by the lesions present after death.

“Copper, in simple salt form, fed to rabbits in amounts up to 1,380 mg. of copper, during a period of 97 days, and injected (copper sulphate and copper amino acids) intramuscularly into rabbits, in amounts up to 55.1 mg. of copper, during periods to 90 days, enters the blood and is found mainly and in largest amounts in the liver, in small amounts in the kidneys, in traces in the lungs and blood, and not at all in either the tuberculous or normal eyes. Copper, in the form of copper sulphate, fed to rabbits in amounts of 1 to 2 cc. of a 1 per cent solution daily for up to 100 days, begun 5 days before infection, has no appreciable effect upon the course of the tuberculosis of the eye, as indicated by the progress of the disease and the final weight of the eye.

“Copper, in simple salt form, injected intramuscularly into rabbits, in amounts of 12 to 42.9 mg. copper, for 37 days, begun on the eleventh day after infection, has no appreciable effect upon the course of the tuberculosis of the eye, as indicated by the development of the disease in the eye.

“Colloidal copper, prepared electrolytically by Bredig's method, injected intravenously into normal and tuberculous rabbits in amounts totaling 9.6 mg., from 4 to 12 days, is found mainly and in largest amounts in the liver, in smaller amounts in the kidneys, in traces in the lungs, and not at all in the normal or in the tuberculous eyes. This distribution of colloidal copper seems to favor the conception that copper in simple crystalline form, fed or injected intramuscularly into the animal organism, does not circulate in this simple form, but rather immediately forms colloidal combinations. If such is the case, this would readily explain its inability to enter tuberculous tissues, since it was found by Wells and Hedenburg that colloids (egg albumin) are not suited as entrants into the tubercle or other necrotic areas.

"Copper, in the form of copper amino acid mixture, does not differ greatly in its systemic (tested in mice with the lethal dose intraperitoneally and intramuscularly about 0.05 to 0.1 mg. copper per mouse of 10 gm.) and local (tested intracutaneously in guinea pigs) toxicity from that of copper sulphate when equal copper contents were compared. Locally, however, a difference existed in the fact that the copper amino acid mixture produced a hemorrhagic necrotic lesion, whereas the copper sulphate produced a simple necrosis. The local non-necrotizing concentration proved to be 0.01 per cent copper, while 0.001 per cent copper still produced a slight duration.

"Copper, in the form of copper oleate (50 per cent) in lanolin by inunction, and copper amino acid mixture applied to the skins of guinea pigs is absorbed, but only to a very slight extent and with uncertainty, as shown by the presence of small amounts of copper in the liver."

About the occurrence of tubercle bacilli in nontuberculous respiratory passages with some secondary findings of capsular diplococci, C. TITZE and H. LINDNER (*Arb. K. Gsndhtsamts.*, 47 (1914), No. 3, pp. 478-490).—The Scharr and Opalka method (E. S. R., 33, p. 357) for collecting mucus for the purpose of diagnosing by bacteriological means the presence or absence of open pulmonary tuberculosis is not deemed an entirely harmless procedure. It can, however, be easily conducted in ordinary practice.

A diagnosis of open tuberculosis can not be made entirely on the basis of the findings of a few tubercle bacilli in the mucus of the respiratory tract, as the clinical signs must be duly considered. In these investigations tubercle bacilli were noted in 4 out of 45 cows which were apparently free of tuberculosis. In the respiratory passages of 5 out of 51 bovines which showed no evidences of disease encapsulated diplococci were noted.

Investigations of hog tuberculosis and its significance for meat hygiene, C. NIEBERLE (*Ztschr. Infektionskrank. u. Hyg. Haustiere*, 16 (1914), No. 1-2, pp. 56-80, figs. 3).—Thirty-four cases of tuberculosis in swine were studied. In every instance histological and bacteriological examinations were made of the carcass and the press juice from the muscular tissues was injected into guinea pigs.

Glässer's findings relative to the existence of two different forms of lymph gland tuberculosis were confirmed; sometimes these were found together in the same lymph gland. Tubercle bacilli in the lymph glands of hogs, as in bovines, developed tubercles from the cytoblastic tissue. The specific cells of the tubercle, i. e., epithelioid cells, which come from the reticulum cells could be detected in the tubercle with ease, but the lymphocytes had no part in the special development process. Additional histological findings relative to development, etc., of the tubercle and the significance of mixed infections with pus organisms are given.

Tuberculosis with typical tubercle formation is most often noted in the lymphatic glands, but changes similar to the so-called rayed caseation noted in bovines are less often observed in cases of this kind. No lymphoid stage seems to be present in this purely infiltrative tuberculosis. In the majority of the cases, the foci macroscopically noticeable in the lungs having the appearance of pneumonic areas were not primary pneumonic areas but simply closely crowded miliary tubercles with lesser or greater secondary pneumonic foci. No extension of a tuberculosis process either in the lungs or lymph glands into the blood or lymph stream was noted.

It is thought that generalization of tuberculosis in swine must occur indirectly by way of the thoracic duct. As the number of tubercle bacilli present in the tuberculous process of swine are few, the filtering power of the lymph glands of these animals is apparently weak.

When the findings are considered from the standpoint of meat inspection, the author believes the so-called tuberculous soft areas, when present, have no significance. In no case when these were present, even in large quantities, did the press juice produce tuberculosis in guinea pigs that received 10 cc. subcutaneously.

Investigations upon the occurrence of antibodies against the *Bacillus abortus infectiosus* in the blood and milk of animals affected with abortion, R. REINHARDT and K. GAUSS (*Ztschr. Infektionskrankh. u. Hyg. Haustiere*, 16 (1915), No. 4, pp. 219-233).—The serum and milk from cows and goats infected with *B. abortus* were found to contain antibodies which could be noted by the complement fixation and agglutination tests. The amount of antibodies present in milk was much less than in serum.

For preparing the milk serum, the milk is treated on the water bath at 45° C. with rennet and filtered. The filtrate is used for the test. The agglutination titer of animals affected with abortion ranged between 1:20 and 1:1,000 and as a rule between 1:100 and 1:500. The complement binding test is regarded positive where the deviation is obtained with 0.2 cc. or less of milk serum. Milk is given the preference over blood serum because it can be easily obtained and on account of the fact that some owners object to having blood examinations made.

Some further experiments in the prevention of bovine epizootic abortion, J. B. BUXTON (*Vet. Jour.*, 70 (1914), No. 472, pp. 507-512).—These experiments in immunization were conducted with rabbits, goats, and cows located on farms where abortion was known to exist. The experiments indicated "that it is possible to produce in susceptible animals a sufficiently high degree of immunity against *Bacillus abortus* by means of suitable doses of a vaccine composed of killed organisms. The figures at present available are not sufficiently numerous to permit of a definite assertion being made. In view, however, of the many advantages which this method of protection possesses over that entailing the use of living organisms in which the element of risk of infection from the vaccine has to be taken into consideration, further work in this direction is of the utmost importance."

The action of arsenical dips in preventing tick infestation, H. W. GRAYBILL (*Jour. Parasitology*, 1 (1914), No. 1, pp. 48, 49).—Experiments in continuation of those published in Bulletin 167. of the Bureau of Animal Industry (E. S. R., 29, p. 287), conducted with a view to determining what protection dipping offers for a period of 3 or 4 days after and the effect upon the ticks, are briefly reported upon. Two experiments were conducted, in the first of which cattle were exposed to infestation on the third and fourth days after dipping, and in the second ticks were applied to animals 5 days after the last of 4 dippings at intervals of 2 weeks and of 1 week.

In the first experiment it was determined that animals dipped once in a dip containing sodium arsenite equivalent to 0.1863 per cent as As_2O_3 were not protected from infestation when ticks were applied 3 days and 4 days after dipping. It was found, however, that the infestation of the dipped animals was light, whereas that of the controls was heavy. Thus it appears that dipping reduced markedly the degree of infestation.

The results of the second experiment indicate that dipping animals 4 times at intervals of 1 and of 2 weeks will not protect them from becoming infested when ticks are applied 5 days after the last dipping. The degree of this infestation did not appear to be reduced in the case of the animals dipped at intervals of 2 weeks but in the case of those dipped at intervals of 1 week the infestation was reduced to a very marked extent. Ticks placed on animals 5 days after the last of 4 dippings at intervals of 1 week and of 2 weeks and permitted to engorge showed no indication of arsenical poisoning.

The chemical control of cattle dipping tanks, C. WILLIAMS (*So. African Jour. Sci.*, 11 (1915), No. 8, pp. 287-296).—The author reports upon investigations of oxidation in arsenical solutions made up in the laboratory and of arsenical fluids in dipping tanks, substantially noted from another source (E. S. R., 31, p. 776).

[Disease of sheep at the Kodiak Station], M. D. SNODGRASS (*Alaska Stas. Rpt.* 1914, pp. 77, 78).—A description is given of an outbreak of a disease in the flock of sheep at the Kodiak Station. It appears that the sheep had been fed partly upon hay of poor quality and somewhat moldy, and that this was apparently the cause of the disease since none were affected after changing to a different hay. Of the 30 ewes affected 17 died and 13 recovered. All of the sheep which survived shed their wool, some losing practically all of it.

Otocariasis in the Bighorn, H. B. WARD (*Jour. Parasitology*, 1 (1915), No. 3, pp. 121-127, pl. 1).—A new sarcoptid mite which heavily infested the ear of a mountain sheep at Estes Park, Colo., is described as *Psoroptes cervina*. It is pointed out that this mite is quite similar to one found in the Pyrenees and in the Congo.

A list of 11 papers referred to is included.

Dipping vat for hogs and dips; hog worms, lice, and mange; hog lots, houses, and water supply, C. A. CARY (*Alabama Col. Sta. Bul.* 185 (1915), pp. 35-58, fig. 1).—Practical information is here supplied as to building a dipping vat (see p. 691), with brief descriptions of the more important parasites of swine, and notes on hog cholera, sanitation, etc.

Combating hog cholera, NEVERMANN (*Berlin. Tierärztl. Wchnsehr.*, 30 (1914), No. 13, Beilage, pp. 19-21; Nos. 25, pp. 441-445, 26, pp. 457-459, figs. 3).—The chief reason given for the great increase in the number of cases of hog cholera in Germany is the failure to report the existence of the disease to the authorities. The veterinarians may also be at fault. Another reason is the shipping of animals from districts where the disease is prevalent and where vaccinations of hogs against erysipelas have taken place. The difficulty in differentiating hog cholera from swine plague in some instances is pointed out. Various recommendations are made for the purpose of improving conditions.

The bacillary pest, typhus, or paratyphus of shoats, L. COMINOTTI (*Clin. Vet. [Milan], Rass. Pol. Sanit. e Ig.*, 37 (1914), No. 23, pp. 989-1004, pls. 2; *abs. in Internat. Inst. Agr. [Rome], Mo. Bul. Agr. Intel. and Plant Diseases*, 6 (1915), No. 2, pp. 267, 268).—The investigations conducted by the author in Italy have been summarized as follows:

"There is also a bacillary disease of pigs in Italy of a morbid type having enzootic characters and a bacillus of the paratyphus B group and which, though distinguished by its epidemiological, clinical, anatomical, and pathological characters from swine fever with a filterable virus, has great affinity with it. The Voldagsen bacillus which causes this form of the disease is distinguished from the swine fever bacillus by certain cultural characters and especially by determined biological characters. The disease produced artificially in young pigs less than four months old by the ingestion of a culture of Voldagsen bacillus is transmissible by contact to healthy young pigs of the same age. Similar infection under the same conditions in pigs of the same age with the swine fever bacillus is not transmissible by contact. In small doses (2 to 5 cc.) the anti-Voldagsen vaccine does not protect the young pigs from infection by contact."

A list of 25 references to the subject is appended.

Casuistical, bacteriological, and patho-anatomical discussions of shoat typhoid with special regard to the distribution of this disease, W. PFEILER and K. HURLER (*Mitt. Kaiser Wilhelms Inst. Landw. Bromberg*, 6 (1914),

No. 4, pp. 261-283; abs. in *Berlin Tierärztl. Wchnschr.*, 30 (1914), No. 31, p. 555).—The authors find that this is a disease more widespread than is usually supposed. In the course of two years it was located in 22 establishments, in which 100 pigs were found infected. See also a previous note (E. S. R., 32, p. 378).

The cause of pernicious anemia of the horse.—A contribution to the problem of the ultraviolet virus, K. R. and R. SEYDERHELM (*Arch. Expt. Path. u. Pharmakol.*, 76 (1914), No. 3-4, pp. 149-201, figs. 10).—After briefly reviewing the literature the authors report at length upon investigations which they have conducted. They find that pernicious anemia of the horse can be produced artificially through the injection of aqueous extracts from the larvæ of horse botflies (*Gastrophilus equi* and *G. hamorrhoidalis*). The effect was found to be due to a toxin to which they have given the name "œstrin," the toxic action of which appears to be specific for the horse and donkey. The œstrin, which is a natural excretion of *Gastrophilus* larvæ, is said to be absorbed through the gastrointestinal canal of the horse. The toxic action of *G. hamorrhoidalis* was found to be very much greater than that of *G. equi*. Pernicious anemia can be produced in the horse through the injection of blood from animals in which the disease has been brought about by the extract from *Gastrophilus* larvæ.

A bibliography of 25 titles is included.

Experimental investigations of the cause of pernicious anemia of the horse, K. R. and R. SEYDERHELM (*Berlin. Tierärztl. Wchnschr.*, 30 (1914), No. 34, pp. 609-612).—A somewhat briefer report of the investigations above noted.

Poultry diseases, E. J. WORTLEY (*New York: Orange Judd Co., 1915, pp. XI+123, figs. 34*).—A popular work dealing with the causes, symptoms, and treatment of diseases of poultry, with notes on post-mortem examinations.

Experiments on cysticerci of *Tænia pisiformis* and of *T. serialis*, J. E. ACKERT (*Jour. Parasitology*, 1 (1915), No. 3, pp. 151-153).—The author's experiments indicate that the dog tapeworms *T. pisiformis* and *T. serialis* will not develop in fowls. Previous investigations show that *T. pisiformis* fails to develop in man and in swine, and that *T. serialis* does not develop in man, swine, cats, or ferrets.

Experimental ingestion by man of cysticerci of carnivore tapeworms, M. C. HALL (*Jour. Parasitology*, 1 (1914), No. 1, pp. 42-44).—Ingestion experiments have led to the conclusion that records of the development of *Tænia pisiformis* in men are erroneous. The other species referred to are *Multiceps serialis*, *T. tenuiformis*, *T. krabbei*, *T. tenella*, *T. ovis*, *T. hydatigena*, and *M. multiceps*. The facts presented indicate the correctness of the generally accepted view that adult cestodes of the genus *Tænia* occurring in Carnivoræ do not occur in man.

Observations on the eggs of *Ascaris lumbricoides*, W. D. FOSTER (*Jour. Parasitology*, 1 (1914), No. 1, pp. 31-36, figs. 4).

A peculiar morphologic development of an egg of the genus *Tropidocerca* and its probable significance, W. D. FOSTER (*Jour. Parasitology*, 1 (1914), No. 1, pp. 45-47, fig. 1).

Rhabditin.—Contribution to a science of nematology, N. A. COBB (*Jour. Parasitology*, 1 (1914), No. 1, pp. 40, 41, pl. 1).

RURAL ENGINEERING.

Practical talks on farm engineering, R. P. CLARKSON (*New York: Doubleday, Page & Co., 1915, pp. XV+223, pls. 17, figs. 21*).—This book, written in popular form, gives simple explanations of several everyday problems in farm engineering and farm mechanics for the use of the practical farmer. The fol-

lowing general topics are discussed: Farm buildings and building materials, farm water supply and sewage disposal, farm power, drainage and irrigation, the cost of road building, the working principles of orchard beaters, and the forms of electricity. A final section gives useful tables for engineering calculations.

Irrigation laws of the State of New Mexico (*Santa Fe, N. Mex.: State Bd. Water Comrs., 1914, pp. 67*).—The text of the laws is given.

The Colorado statute inch and some miner's inch measuring devices, V. M. CONE (*Colorado Sta. Bul. 207 (1915), pp. 3-16, figs. 5*).—This bulletin, based on a cooperative agreement between the Office of Experiment Stations and the Colorado Station, reports the results of a series of experiments on box tubes, thin-edged orifices with free flow, and the so-called Uncompahgre orifice, the object of which was to secure definite information concerning the Colorado statute inch and experiments on the so-called Azusa hydrant, a miner's inch device used in southern California (E. S. R., 32, p. 683).

In the box-tube experiments the boxes used were 16 ft. long and were given a descending grade of $\frac{1}{8}$ in. to the foot, the discharge end being, therefore, 2 in. lower than the intake end. Metal strips $\frac{1}{8}$ in. thick were placed around the intake end of each box so the inside dimensions of the orifice could be accurately determined. The inside depth of the box was practically 6 in. in every case and the water surface was 5 in. above the top of the orifice. A thin metal slide was made to fit between the metal strips on the end of the box, and this was adjusted to give any width of opening from 2 to 16 in. It was found in general that the discharge for any certain size of orifice increased as the width of the boxes increased, except for a slight reduction when the orifice was nearly the same size as the box. "The number of statute inches to one second-foot, therefore, decreases with a decrease in the size of the box, and also the number of statute inches to one second-foot increases as the size of the orifice is increased, which means that the discharge of each square inch of orifice decreases as the size of the orifice is increased. This is the opposite to the results obtained with thin-edged orifices having free flow. Box tubes with orifices from 12 to 96 sq. in. gave discharges with the number of statute inches to 1 second-foot varying from 33.7 to 38.4, and a greater number would no doubt be obtained for still larger orifices."

In the experiments with thin-edged orifices with free-flow sizes of orifice ranging from 1 in. square to 6 in. deep by 6 in. wide were used. The depth of water above the top of the orifice was 5 in. in every case. A concrete box was used having a cross section of 10 ft. by 6 ft. It was found that the discharge for each square inch of opening increased as the size of the opening was increased. "For a constant depth of orifice the discharge per square inch of opening is the greatest for a width of 1 in., decreases as the width is increased for a few inches, or approximately until the orifice is square for the larger sizes of orifices, and then increases as the width is increased. The number of statute inches to 1 second-foot varies from 42.9 to 35.5, but for the sizes of orifices commonly used for measuring water to the individual irrigator it is probable the value would be from 36 to 37, and as low as 35 might be obtained for wider orifices. . . . The discharge through full contraction, thin-edged, free-flow orifices having a depth or vertical dimension of 6 in. and a head of 5 in. above the top of the orifice, is represented by the formula

$$Q = 0.169b - 0.06 + \frac{0.06}{1 + 0.015b^{2.6}}$$

in which Q is in second-feet and b is the breadth or horizontal dimension of the orifice in inches."

In the experiments with the Uncompahgre orifice it was found that the discharge was greater than through the sharp-edged orifices with free flow on account of the comparatively high velocity of approach in the orifice box.

In the experiments with the Azusa hydrant it was found that the actual discharges were from 2 to 6.4 per cent less than the intended discharges. "However, in actual practice the orifices become larger, due to the edges rusting, and the head of water is usually greater than 2 in., because a small amount is allowed to pass over the spillway or overflow."

While the value of the Colorado statute inch has been assumed to be 1/38.4 part of a cubic foot per second, it is concluded that this does not constitute a legal definition of the statute inch, since the number of statute inches to the second-foot may vary from at least 33.7 to 42.9 and still conform to the law in every particular.

Sixth biennial report of the state engineer to the governor of North Dakota for the years 1913-14 (*Bien. Rpt. State Engin. N. Dak., 6 (1913-14), pp. 157, pls. 11*).—This report covers the operations of the state engineer's office during 1913 and 1914, giving special attention to drainage, highways, stream measurements, and coal mining.

Irrigation and water conveyance and diversion (*Verlag Burgerl. Openb. Werken Nederland. Indië, 1912, pt. 4, pp. IX+163, pls. 16*).—This reports the progress of irrigation and water conveyance and diversion works for the year 1912.

The practical operation of irrigation works, S. G. PORTER (*Dept. Int. Canada, Irrig. Branch Circ. 1 (1914), pp. 10*).—This is a discussion of practical points in irrigation.

Report on irrigation experiments at Rochester, New York, conducted jointly by Rochester Railway and Light Company and New York State College of Agriculture at Cornell University, season of 1913, E. H. FISHER (*Manuscript (not printed), pp. 19, blue prints 10, photographs 10*).—This manuscript contains the results of irrigation experiments with raspberries, blackberries, beans, peaches, and apples, using furrow irrigation and the so-called Skinner overhead irrigation. The furrow system was used with peaches and apples and the overhead system with the beans and berries.

While the results obtained are for one season only, it is stated that they were in general fairly satisfactory. It is thought to be reasonably certain that irrigation will pay on berries and that there is some hope of success on other crops.

[Irrigation experiments], GERLACH (*Mitt. Kaiser Wilhelms Inst. Landw. Bromberg, 6 (1915), No. 5, pp. 328-359*).—Four years' irrigation experiments with different field and truck crops on light loamy sand soils are reported.

During the four years irrigation on light soils was generally accompanied by marked increases in crop yield, particularly in the years with greater rainfall. In such years certain crops were especially responsive to irrigation, particularly those whose most luxuriant development occurred during short dry periods.

It was further found that on these light soils fertilization favorably influenced the utilization of irrigation water.

Problems relating to the tile drainage of irrigated lands, H. C. MILLER (*West. Engin., 5 (1915), No. 10, pp. 431-434, figs. 2*).—The design and construction of a tile drainage system for irrigated land is discussed and methods and a chart for calculating sizes of tile are given.

Contributions of the chemist to the potable water industry, W. P. MASON (*Jour. Indus. and Engin. Chem., 7 (1915), No. 4, pp. 289, 290*).—This article

explains especially how chemical and bacteriological examinations supplement one another in determining the character and quality of potable water.

The treatment of waste waters from tin and lead mines, gut factories, and piggeries, G. B. KERSHAW (*Surveyor*, 47 (1915), No. 1209, pp. 404, 405).—This article states that the sewage from piggeries is often ten to fifteen times as strong as domestic sewage of average strength. "The total dry-weather volume of liquid sewage per pig may amount to some 4 to 5 gal. daily, and during rainy days there will be a considerable addition to this quantity. . . ."

"Preliminary treatment of such a strong liquid is best carried out by precipitation with lime in settling tanks, constructed in duplicate, each of them having a capacity equivalent to about 1½ days' flow of sewage. The tank liquor is best treated on deep percolating filters of medium-sized material, and the filter effluent should be passed through shallow sand-straining filters. Unless a very low rate of treatment is adopted—say 20 to 25 gal. per cubic yard per 24 hours—a good effluent can not, as a rule, be uniformly obtained, and in general it is much better, wherever practicable, to dilute the tank liquor with from two to three times its volume of clean water, and then to filter at a rate of about 75 gal. per cubic yard per 24 hours."

The separation and removal of microbes suspended in water by a stream of air, A. TRILLAT and M. FOUASSIER (*Compt. Rend. Acad. Sci. [Paris]*, 158 (1914), No. 7, pp. 518-521; *abs. in Chem. Zentbl.*, 1914, I, No. 13, pp. 1294, 1295; *Wasser u. Abwasser*, 8 (1914), No. 8, p. 481).—An experiment is described which showed that with a water of constant surface tension containing different microbes in suspension the admission of a stream of air not only forced the microbes to follow the air but effected their separation according to their size.

Dynamite experiment, F. G. SPRING (*Agr. Bul. Fed. Malay States*, 2 (1914), No. 11, pp. 297, 298).—The results of experiments conducted at the Experimental Plantation at Kuala Lumpur on soil of a poor lateritic nature on which the rubber plants were backward in growth are reported.

Three rows, each containing 34 trees were used, two rows being kept as controls. The cartridges were placed at a depth of 2½ ft. below the ground surface, one between two trees 12½ ft. apart. After seven months and a few days the average increase in girth was 2.56 in. in the dynamited row, and 1.81 and 1.62 in. in the control rows.

On the use of explosives and of the blow lamp in the garden, H. E. DURHAM (*Jour. Roy. Hort. Soc.*, 40 (1914), No. 1, pp. 7-18).—This report is in two parts.

The first, dealing with the use of explosives, briefly describes methods of procedure in blasting soils and reports experiments made to determine the value of explosives for loosening the soil on small areas, such as intensely cultivated gardens.

Cheddite cartridges with 2, 1½, 1, and ½ oz. charges were placed 3 ft. apart and at a depth of 3 ft. Potatoes responded in a marked manner to the use of the explosive, the ½-oz. charges being accompanied by about 15 per cent increase, the 1-oz. by 43 per cent, and the 2-oz. by 88 per cent. Cauliflower and cabbages showed no appreciable difference in blasted and unblasted soils. With peas the number of plants was much smaller on the unblasted side but they blossomed and matured a week earlier than on the blasted soil. Carrots, onions, and Scorzonera gave a greater number of plants and germinated and developed much better on the blasted soil. This was particularly marked in the case of Scorzonera.

In the second part the use of the plumber's blow lamp for the destruction of weeds and insects is briefly described.

Blast furnace slag in concrete, W. A. AIKEN (*Iron Trade Rev.*, 55 (1914), No. 1, pp. 31, 32; *abs. in Indus. Engin. and Engin. Digest*, 14 (1914), No. 9,

pp. 380, 381).—An extended series of tests in which five lots of 100 each of 6-in. cubes, mixed in the proportions of 1 part cement, 2 parts sand, and 4 parts blast furnace slag and passing the $1\frac{1}{2}$ -in. sieve but retained on the $1\frac{1}{4}$ -in. sieve, were crushed at periods of 28 days, 3 months, 6 months, 9 months, and 1 year, respectively, is reported.

The results indicate that slag may be employed as an aggregate in competition with broken stone or gravel. "From the actual strength of the concrete developed in these tests, its weight per cubic foot, the recognized solubility of slag which permits it to act as a pozzolanic material, its alkaline nature which is especially conducive to rust-proof in the case of reinforced concrete, and from the relatively high combined percentages of silica, alumina, and iron, which make for permanency of the resulting concrete, the conclusion is that slag is satisfactory for use as an aggregate in concrete."

Oil-mixed Portland cement concrete, L. W. PAGE (*U. S. Dept. Agr. Bul. 230 (1915)*, pp. 26, pls. 6, figs. 7).—This is a revision of Office of Public Roads Bulletin 46 (E. S. R., 28, p. 85) and presents the results of more recent laboratory and service tests of oil-mixed concrete.

The conclusions so far reached are summarized as follows: "The admixture of oil is not detrimental to the tensile strength of mortar composed of 1 part cement and 3 parts sand when the oil added does not exceed 10 per cent of the weight of the cement used. The compressive strength of mortar and of concrete suffers slightly with the addition of oil, although when not to exceed 10 per cent of oil is added the decrease in strength is not serious. Concrete mixed with oil requires a period of time from 50 to 100 per cent longer to set hard than does plain concrete, but the increase in strength is nearly as rapid in the oil-mixed material as in the plain concrete. Concrete and mortar containing oil admixtures are almost perfectly nonabsorbent of water and are therefore excellent materials to use in damp-proof construction. The addition of oil, however, does not appear to increase to any great extent the impermeability of concrete subjected to heavy water pressure, and this method alone will probably not make the concrete proof against the actual percolation of water through the mass Laboratory tests show that oil-mixed concrete is just as tough and stiff as plain concrete, and, furthermore, its elastic behavior within working limits of stress is identical with that of plain concrete. The bond between concrete and plain-bar reinforcement is decreased by the use of oil in the concrete, but when deformed bars, wire mesh, or expanded metal is used there is no apparent decrease in the bond."

A series of experiments to determine what effect the addition of oil has in retarding the action of alkali salts on the cement indicated that the action of a 10 per cent solution of sodium sulphate was materially retarded by the addition of 5 to 10 per cent of oil to a 1:3 mixture.

Of 29 replies to letters inquiring as to the success or failure obtained by users of oil-mixed concrete, only three were wholly unfavorable.

Portland cement concrete pavements for country roads, C. H. MOOREFIELD and J. T. VOSHELL (*U. S. Dept. Agr. Bul. 249 (1915)*, pp. 34, pls. 11).—It is the purpose of this bulletin to supply information on the subject of Portland cement concrete pavements for the use of highway engineers and others interested in the improvement of public roads.

It is stated that the economic efficiency of concrete roads is undetermined at present, but the indications are that this type of construction will prove to be well suited for certain conditions. The principal advantages possessed by concrete pavements are briefly stated as follows: "(1) As far as can be judged, they are durable under ordinary suburban and rural traffic conditions. . . . (2) They present a smooth, even surface, which offers very little resist-

ance to traffic. . . . (3) They produce practically no dust and may be easily cleaned. (4) They can be maintained at comparatively small cost until renewals become necessary. (5) They may be made to serve as an excellent base for some other type of surface when resurfacing becomes desirable. (6) They present a pleasing appearance." The principal disadvantages are "(1) They are somewhat noisy under horse traffic. (2) There is no method of constructing necessary joints in the pavements which will entirely prevent excessive wear in their vicinity. Furthermore, joints do not altogether eliminate cracking, and wherever a crack develops it must be given frequent attention in order to prevent rapid deterioration of the pavement. (3) They can not be as readily and effectively repaired as many other types of pavements. . . .

"The one-course type of concrete pavement is greatly to be preferred to the two-course type, but there are conditions under which the adoption of the two-course type of construction may be justified. The proportion of cement to the sand and coarse aggregate combined should not be less than about 1:5, and the proportion of sand to coarse aggregate should not be less than $1\frac{1}{2}$:3, nor greater than 2:3. Ordinarily, when gravel is used as coarse aggregate, the proportions may be made 1 part of cement to $1\frac{1}{2}$ parts of sand to 3 parts of gravel, and when crushed stone is used as coarse aggregate 1 part of cement to $1\frac{1}{4}$ parts of sand to 3 parts of crushed stone.

"All types of contraction joints which have yet been devised require careful and frequent attention in order to prevent rapid deterioration of the pavement in their vicinity. It appears that better results are obtained by spacing the joints at an angle of about 75° to the center line of the road than when they are placed at an angle of 90° . Thin bituminous wearing surfaces for concrete pavements can not be economically justified at present. . . .

"Intelligent engineering supervision is absolutely essential in concrete pavement construction, because defective materials or workmanship can not be readily repaired after the pavement is completed, and they are not usually apparent until the pavement has been in use for some time."

Specifications are given which are believed to typify the best practice which has been developed in concrete pavement construction.

Vitrified brick pavements for county roads, V. M. PEIRCE and C. H. MOORE-FIELD (*U. S. Dept. Agr. Bul. 246 (1915), pp. 38, pls. 10, figs. 3*).—This is a revision of Department Bulletin 23 (E. S. R., 30, p. 86).

Notes on the width, alignment, grade, and drainage features of the designing of country roads, R. A. MEEKER (*Engin. and Contract., 42 (1914), No 15, pp. 346, 347*).—This is a brief summary of important details connected with the preparation of plans for rural road improvements under New Jersey conditions.

It is stated as axiomatic that the width of roads should be in multiples of 8 ft., and that in order to obtain a roadway of sufficient width to accommodate travel passing in both directions 24 ft. may well be taken as the minimum allowable width. The important considerations in alignment are pointed out as direct distance, grades, and the economic features of grading. Grade is considered to be the most important economic feature in road design. As regards drainage, it is thought that for earth roads a fall of 1 in. per foot from the center to the gutters, for water-bound macadam $\frac{3}{4}$ in. per foot, and for bituminous concrete $\frac{1}{2}$ in. per foot is sufficient. For country roads gravel or plain macadam is thought to be sufficient for surfacing.

Progress reports of experiments in dust prevention and road preservation, 1914 (*U. S. Dept. Agr. Bul. 257 (1915), pp. 44*).—This bulletin reports the results from a number of experiments in dust prevention and road preservation conducted by the Office of Public Roads in 1914, a similar report for 1913

having been noted (E. S. R., 31, p. 686). The materials used and methods employed in the experiments, the several kinds of roads and varying conditions of traffic, and analyses of materials and cost data are also given.

A second series of experimental bituminous treatments of coralline rock roads in Dade County, Fla., using light and heavy oils and two water-gas tar products, "clearly demonstrated that the greatest difficulty to be overcome in any future large-scale construction of bituminous coralline rock roads is the harmful effect of rains on the prepared surface before the application of the bitumen. The high cementing power of the rock causes it to bind strongly when wet unless the dust is entirely removed in the screening. The surface is thus rendered more or less impervious, and the treatment becomes in effect only a surface treatment. This difficulty may be met by performing such work in the dry season of the year or by keeping at all times the prepared surface work and the bituminous application well together." After a year of service none of these experiments showed any decided evidence of failure. In connection with these experiments a section of ordinary coralline rock surface was treated with calcium chlorid at the rate of 1.49 lbs. per square yard, the purpose being to maintain a damp surface on the coralline rock road. After several weeks of wear the surface was damp at all times, but pitted to some extent, showing bare rock in spots.

Experiments were also conducted at West Palm Beach, Fla., with oil, tar, oil asphalt, and coralline rock to develop a more economical and durable road surface than is obtainable by the use of coralline rock under ordinary methods of construction. Experience gained from the construction in the experiments at Miami, Fla., previously noted, and from their inspection after long usage by traffic "showed conclusively that the best method of treatment involved the use of rock from which the finer particles had been removed to provide for uniform penetration of the bitumen. . . . The general method of construction preparatory to the application of the bitumen was, in brief, as follows: The preparation of a thoroughly compacted subgrade parallel to the finished surface and composed of the rock originally in the roadbed; upon this, a course of screened rock with a uniform loose depth of 3 in., lightly compacted to allow a maximum penetration of bituminous material." An inspection of these experiments the following year showed that the residual asphaltic petroleum was used with uniformly good results in one case, while in a second case the section, although in good condition and free from any wearing defects, presented a varied appearance which is attributed to the varied weather conditions under which the experiment was constructed. The refined coal-tar experiments were in good condition in one case, but in a second case the tar had become hard and friable, necessitating a surface treatment to prevent wear. One oil asphalt section was in excellent condition, while a second section had a mottled appearance, due to bleeding of the bitumen to the surface. A water-bound coralline rock macadam section showed a smooth, unbroken surface true to cross section. A comparison of this experiment with the bituminous-bound experiments indicated that the water-bound macadam had worn down about $\frac{1}{4}$ in. below the adjacent bituminous-bound section.

Supplementary reports of experiments at Miami, Fla., with oil and coralline rock in 1913; on Rockville Pike, Md., with tar and asphaltic petroleum in 1913; at Washington, D. C., with surface treatment with tar preparations and oils in 1912; at Chevy Chase, Md., with bituminous concrete, cement concrete, oil-cement concrete, vitrified brick, and bituminous surface treatments on concrete in 1912; at Chevy Chase, Md., with bituminous construction and surface treatment in 1911; at Jamaica, N. Y., with oil-cement concrete, oil asphalt, tar, and fluxed

native asphalt in 1911; at New York, N. Y., and Ridgewood, N. J., with oil-cement concrete in 1910; at Boise, Idaho, with oil-gravel macadam in 1910; at Ames, Iowa, with oil-asphalt gravel in 1910; at Knoxville, Tenn., with tar and oil preparations in 1910; at Youngstown, Ohio, with slag, slag and lime, slag and waste sulphite liquor preparation, and slag and tar in 1909; at Newton, Mass., with asphaltic preparations, tar preparations, residual oil, and molasses-oil-lime in 1908; at Garden City, Dodge City, Bucklin, and Ford, Kans., with sand-clay in 1908; and at Bowling Green, Ky., with Kentucky rock asphalt in 1907 are also included.

Proceedings of good roads institute held at University of North Carolina, March 17-19, 1914 (*N. C. Geol. and Econ. Survey, Econ. Paper 39 (1914), pp. 117, pls. 4, figs. 15*).—This report includes the following special articles: Road Surveying and Mapping, by T. F. Hickerson; The Use of the Abney Hand Level, by T. F. Hickerson; Economics of Road Construction, by W. S. Fallis; Sand Clay and Topsoil Roads the Economic Roads for North Carolina, by J. H. Pratt; Natural Sand Clays in the North Carolina Piedmont Belt, by J. E. Smith; Dirt Roads, by J. H. Pratt; Drainage of Roads, by T. F. Hickerson; County Highway Bridges, by J. M. Ambler; Culverts, by R. T. Brown; Road Machinery Required in County Road Construction, by N. C. Hughes, jr.; Road Surfacing Materials in North Carolina, by C. Cobb; and Lignin Liquor as a Binder for Macadam, Gravel, and Sand-clay Roads, by G. N. Moore.

Steam as the by-product of internal combustion engines, J. B. MERIAM (*Gas Engine, 16 (1914), No. 11, pp. 704-709, figs. 6*).—The author shows by discussion and experiment that if an inclosed cooling system is used and only steam is allowed to escape, all of the water used must eventually be turned into steam. The total heat units of the fuel lost to the water jackets are fully recovered and restored to the steam. In tests of such a system no difficulty or detrimental effects were experienced when operating the engine at maximum load with the jackets under full steam pressure and temperature. "Another marked advantage in this process is found in the fact that the thermal efficiency of the engine is improved so that the fuel consumed is at least 2 per cent less at maximum load and fully 15 per cent less at one-fourth load."

Increasing output of gas engines (*Power, 40 (1914), No. 10, pp. 340, 341, figs. 4*).—A method is described for increasing the output of gas engines, in which the burnt gases are first scavenged and the working charge then admitted under pressure, thus increasing the weight of the charge and consequently raising the mean effective pressure.

Gas-engine valve setting, G. W. MUENCH (*Power, 40 (1914), No. 15, pp. 547, 548, fig. 1*).—This paper discusses the causes leading to altered valve timing and gives simple directions for the proper resetting of the valve gear.

Oil engines for pump irrigation and the cost of pumping, G. E. P. SMITH (*Arizona Sta. Bul. 74 (1915), pp. 379-450, pls. 4, figs. 16*).—This bulletin describes fuel oils and their tests and oil engines of the Diesel, modified gasoline engine, and hot-ball groups, reports tests of the last two types as to fuel economy, capacity, speed regulation, and power development, discusses oil engine characteristics based on the tests reported, and gives data on the cost of pumping for irrigation.

It is pointed out that gasoline is too expensive a fuel for pumping engines in Arizona. Cheap distillates of from 39 to 44° Baumé with low flash point are deemed the most advisable to use at the present time, these being preferably purchased in carload lots.

It is thought that Diesel engines are not adapted to farm conditions. "Four-cycle gasoline engines with electric ignition and suction fuel feed can be modified to burn heavier distillates successfully by feeding water with the charge.

Preheating of the charge, also, is necessary in cold weather, and the heavier distillates require higher compression and earlier ignition than gasoline in order to give the best results. The water feed is the most important factor. . . . Gasoline engines already in service can be altered by replacing the fuel mixer and the exhaust block with specially designed ones, or by adding a homemade device for feeding water into the air inlet pipe. . . . The effects of the water in the charge are softened explosions, more complete combustion of the fuel, a cleaner cylinder, cleaner valves, uniform temperature with reduced loss of power in the jacket water, and no preignition. Despite the loss of power in the heat of vaporization of the feed water, the fuel economy of the engine is not lowered.

"Two-cycle engines with hot-ball ignition and fuel injection at the end of the compression stroke can be operated on low gravity distillate, even down to 30° Baumé for small engines, and to 24° Baumé for large engines, provided the compression pressure is increased to 180 lbs. per square inch. As in the case of 4-cycle engines, water feed is essential except perhaps when the engine is carrying less than one-third of its full load. . . . Forced-feed lubrication is necessary for hot-ball engines and is desirable for large 4-cycle engines. Pump circulation gives much better results than the thermosiphon system for hot-ball engines.

"Fuel economy of 9 or 10 brake horsepower-hours per gallon of fuel oil is possible with farm engines of either type, assuming the engine to be in good condition. In the average ranch pumping plant the fuel economy is about 6 or 7 horsepower-hours per gallon. The determining factor of fuel economy is the adjustment of the fuel valves. . . . Nearly all oil engines are operated with the fuel valves opened wider than is necessary. . . . Mechanical losses of power in an engine are most important when the engine is only partly loaded. An engine should be run at from three-quarters to full load. A purchaser should compute his power requirements carefully and then add about 15 per cent to determine the size to buy. At altitudes of from 3,000 to 5,000 ft. from 25 to 30 per cent should be added to the computed capacity. . . . The piston displacement per minute per horsepower is the best indication of the capacity of an engine. . . . The quantity of humidifying water should be controlled by the governor. . . .

"Four-cycle oil engines with electric ignition are proving to be quite as reliable as gasoline engines. The combustion of the fuel oil is perfect and there is no exhaust smoke. The explosions can be timed perfectly and they occur with great regularity. Compared with gasoline, the only disadvantage in burning tops is with respect to starting in cold weather, when it is necessary to run for from one to five minutes on gasoline and then change over to tops.

"The experience had with hot-ball engines in Arizona to date has been unsatisfactory. The combustion is imperfect, usually bad. Hot-ball ignition has serious disadvantages. The evil effects of leaky compression are very great. Pump lubricators, water-circulating pumps, and friction-clutch pulleys are required even on small engines. On careful analysis the hot-ball engines do not have any advantage in simplicity. Their useful life will be less than that of 4-cycle engines. . . .

"The use of tops in place of engine distillate decreases the cost of pumping from 20 to 40 per cent. The cost of pumping on a 40-ft. lift with 4 ft. depth of application varies from \$8 to \$20 per acre, according to whether the plant is used much or little. Under the most favorable conditions the cost of pumped water is no greater than the cost of river water. The cost of pumping on a 100-ft. lift with 4 ft. depth of application varies from \$20 to \$40 per acre.

Ranches dependent upon so high a lift should be devoted to high-priced crops, such as orchard fruits and vegetables, or to crops whose water requirements are low, such as millet, sorghums, corn, and sugar beets. Not over one-fourth of the acreage should be used for alfalfa. Electric power at the rates prescribed by the Arizona Corporation Commission is much more costly than the use of oil engines. The largest item of cost is the fixed charges. In order to reduce these charges the plant should be used all possible. Never shut down at noon or at night through the irrigating season from March to July. One pumping plant should serve two or more ranches."

Testing small centrifugal pumps, M. R. BLISH (*Power*, 41 (1915), No. 11, pp. 370-373, figs. 7).—Methods and apparatus for making capacity tests of centrifugal pumps are described and the apparatus is illustrated.

Sizes of motors driving centrifugal pumps, E. M. MARSHALL (*Power*, 40 (1914), No. 11, pp. 383, 384, fig. 1).—The calculations necessary for determining the proper size of motor to drive a centrifugal pump under given conditions of delivery and head are outlined and a chart for simplifying these calculations is given.

A graphical process for choosing the electrical drive for pumps, M. GAZE (*Jour. Gasbeleucht.*, 57 (1914), pp. 726-730, figs. 11; *abs. in Wasser u. Abwasser*, 9 (1914), No. 2, p. 44).—A graphical process for facilitating the choice of electrical driving equipment for pumping machinery is described.

Electricity for the farm, F. I. ANDERSON (*New York: The Macmillan Co.*, 1915, pp. XXIII+265, pls. 8, figs. 42).—This book is intended primarily to give the farmer a practical working knowledge of electricity for use as light, heat, and power on the farm. It is divided into three parts with reference to power sources, namely, water power; electricity; and gasoline engines, windmills, etc.

The following chapters are included: A working plant; a little prospecting; how to measure water power; the water wheel and how to install it; the dynamo, what it does, and how; what size plant to install; transmission lines; wiring the house; the electric plant at work; gasoline-engine plants; the storage battery; and battery-charging devices.

Electro-culture (*Sci. Amer. Sup.*, 79 (1915), No. 2051, pp. 258, 259).—This is a resumé of the literature and a summary of facts from scattered sources.

It has been found that the experiments of the past fall naturally into five classes, differing principally in the method of application of electrical energy. These are (1) illumination by electric light, (2) conduction of atmospheric electricity from an elevated collector to an electrode in the soil or to discharge points above the plants, (3) constituting the soil the electrolyte of a voltaic cell by burying in it two plates of dissimilar metal connected by a conductor, (4) passing current from an external source through the soil between electrodes buried therein, and (5) production of a silent or glow discharge through the air from overhead antennæ to the soil.

"The impression gained from the literature of electro-culture is that the last word is by no means said. From the nature of the publications it would appear that the individual investigations have been too cursory. There has been too little systematic variation of conditions, and especially of the electrical conditions. It seems highly desirable that a much more extensive investigation, providing the possibility of trying different intensities of electrification under various conditions of cultivation, irrigation, etc., all during the same season, should be carried out. It is significant that the only investigator to attempt an extended examination of the field was able to locate and eliminate many faults in his method, and thus obtain good results in the end in almost every case, often reversing his previous experience."

The silo and its use, C. H. ECKLES (*Missouri Sta. Bul.* 133 (1915), pp. 3-19, figs. 5).—This bulletin gives general information regarding silos and silage and briefly describes the stave, concrete, plastered, and tile silo types.

Hog, calf, sheep, and goat dipping vat, C. A. CARY (*Alabama Col. Sta. Bul.* 185 (1915), pp. 38-41, fig. 1).—Directions, with a plan, for constructing a concrete dipping vat are given.

Poultry house construction, R. E. JONES and L. E. CARD (*Connecticut Storrs Sta. Bul.* 81 (1915), pp. 31-55, figs. 16).—The purpose of this bulletin is to present in concise form some of the essential points to be considered in poultry house construction and to give plans and specifications for some of the houses that have given good results at the station, including the so-called contest house, the Gilbert farm poultry house, and the colony brooder house. The Connecticut trap nest and dry mash hopper are also described.

Features of construction that are especially emphasized are proper window space, ventilation, and floors. "All windows or openings should be so located that the sun may reach every part of the interior of the house as many hours as possible during each day. A safe proportion of glass to use is 1 sq. ft. of glass to each 12 sq. ft. of floor space. . . . A curtain made of very thin unbleached muslin will allow fresh air to pass in and the moist, foul air to pass out, thus furnishing plenty of ventilation without drafts. These curtains are for use only during cold weather and should always be open during the day except when it is necessary to close them for protection against storm. Windows may be placed either in the front or ends as best suits the type of house, but the curtain area should be as near the center of the front as possible in order to prevent the wind blowing in one end of the house, sweeping across the floor, and out at the other end. A safe rule to follow in estimating the curtain area is to allow 1 sq. ft. of cloth to each 6 sq. ft. of floor space. . . . The hens seem to prefer a dirt floor and it provides a natural dust bath at all seasons of the year. . . . It is best to put a layer of sand 5 or 6 in. deep over the dirt as this will help to keep the house dry and at the same time will prevent excessive dust. For a permanent, moisture-proof and rat-proof floor, concrete well insulated with a layer of tarred paper is best. All concrete floors should be covered with a layer of sand and a thick layer of litter to make the birds more comfortable and to facilitate cleaning. A board floor can be used to best advantage in a portable house that is likely to be moved at any season of the year.

The main consideration in the selection of material for a poultry house is that the house must be tight on three sides.

Advisory pamphlet on camp sanitation and housing (*San Francisco: Com. Immigr. and Housing Cal., 1914, pp. 54, figs. 43*).—This pamphlet prepared for owners and superintendents of labor camps on hop and other ranches, contains specific suggestions pertaining to the housing of men in camps, with particular reference to sanitation. The main points covered are location, size and area of sleeping, cooking, and eating quarters, water supply, garbage and refuse disposal, toilet and bathing facilities, flies and manure, and mosquitoes and malaria.

Domestic hygiene: The septic tank, R. SOUÈGES (*Bul. Sci. Pharmacol., 21 (1914), Nos. 8-9, pp. 470-476; 10-12, pp. 510-539, figs. 4*).—The first part of this article discusses physical, chemical, and biological methods for the purification of domestic sewage, taking up particularly the biological action which is generally supposed to occur in septic tanks and filters. The second part deals more particularly with the disposal of residential sewage and sketches the history of small septic tank systems for this purpose.

RURAL ECONOMICS.

Outlets and methods of sale for shippers of fruits and vegetables, J. W. FISHER, JR., J. H. COLLINS, and W. A. SHERMAN (*U. S. Dept. Agr. Bul. 266 (1915), pp. 28*).—This bulletin attempts to show the available outlets for the individual producer in marketing his fruits and vegetables and how he can get in touch with these outlets. The authors call attention to the following points in summarizing:

“Cooperation is desirable between grower and grower, and grower and consumer, but is needed especially between the producer and the distributor. The grower must realize the necessity of living up to an agreement and doing business on a businesslike basis.

“The grower should keep in constant touch with the market, either through the newspapers, trade papers, private firms, auction reports, or by telephone, telegraph, or mail. In offering goods for sale, shippers should give definite and detailed information regarding the prospective shipments, such as the probable date of shipment, the commodity, number of packages, kind and size of package, quantity and quality of each variety, whether freight or express shipment, and the road and route. . . .

“Personal visits to the market patronized will enable the grower to obtain the proper market perspective. He will see the difficulties under which the distributors work, he will see his products in competition with those from the most highly specialized districts, and he will learn the necessity of good quality, honest packing, and standardization.

“Before establishing market connections, the dealer’s commercial standing should be studied very carefully. Commercial credit agencies, trade papers, chambers of commerce, and local bankers all can be of assistance in this respect.

“The producer can sell either individually or cooperatively. Cooperative associations assume all marketing responsibilities for the individual shipper and are in a much better position to keep in touch with the market and to secure an equitable distribution.

“Sales direct to the consumer are not always advisable owing to the difficulties of transportation and the problems of collections and bad accounts. Direct-to-the-consumer sales are usually possible only with highly specialized commodities of small bulk. . . .

“Under present methods of distribution most car-lot shipments must be sold through wholesale distributing agencies.

“Sales to country merchants, country collecting agents, country buyers of special products, and traveling buyers are desirable in that the grower deals with the buyer in person and receives cash at the time of sale. . . .

“One advantage of selling goods f. o. b. destination is that although they are liable to rejection in case of damage in transit or a decline in the market, there is at least the prospect of a buyer, and, with reasonable allowances made, the car usually will return a greater profit than if it had been shipped to the market unordered.”

Methods of wholesale distribution of fruits and vegetables on large markets, J. H. COLLINS, J. W. FISHER, JR., and W. A. SHERMAN (*U. S. Dept. Agr. Bul. 267 (1915), pp. 28, figs. 2*).—The authors of this bulletin attempt to explain certain general practices at large distribution centers which receive fruit and vegetables in car-lot quantities.

“The widening distance between producer and consumer has called into existence the middleman of to-day. The fact that the middleman has certain useful functions to perform makes it inadvisable to eliminate him without arranging for some other agency to assume his duties.

"The shipper who starts a car toward market should notify the consignee in such detail that prompt disposition of the goods may be made after the arrival of the car. . . . As perishables should always be inspected promptly on arrival at destination, the shipper should give shipping instructions which permit inspection without unnecessary delay at destination. . . .

"In case a buyer rejects a car the shipper has the option of selling elsewhere or making an allowance to the original purchaser in order to close the transaction immediately. Claims against railroads should be filed in proper form and supported by a presentation of the facts in the case. . . .

"Brokers act as shippers' or buyers' agents. They handle car lots only and offer their services at very low rates. While many brokers are charged with abusing their privileges, they often save the shipper several times the brokerage fee by insuring the acceptance of goods at destination.

"Fruit auctions sell goods for shippers, dealers, and others who have local representatives to withdraw offerings if prices are unsatisfactory. They secure their revenue by levying definite assessments against each package sold, and by attracting buyers and stimulating competition often expand the market for particular commodities. . . .

"The commission merchant receive goods on consignment and acts as the shipper's agent in disposing of these products to the jobbing and retail trade. While the commission merchant is viewed with much suspicion by many shippers, he nevertheless is a very important factor in that he furnishes to shippers the services of a skilled specialist in salesmanship.

"The jobber acts as a secondary distributor, buying from car-lot receivers and selling largely to the retail trade. His chief usefulness lies in facilitating rapid distribution of highly perishable products and in preventing a congestion of business on large wholesale markets.

"Public markets are not important in distributing fruits and vegetables arriving at market in car lots, but do offer direct outlets for neighboring producers. . . .

"Losses and wastes are a very heavy tax on food distribution. The prevention of much needless waste would reduce present marketing costs very materially.

"One of the most practical steps the shipper can take to better his condition is to familiarize himself with business practices and to secure a better knowledge of the way his produce is handled on the market."

A glossary of trade terms is included.

Markets for potatoes (*Univ. Oreg. Bul., n. ser., 12 (1915), No. 5, pp. 41*).—This study was made in an effort to determine possible markets and methods for making the production of potatoes in Oregon more profitable. The author concludes his discussion with the following suggestions:

"A solution of the problem of profitable potato growing and marketing might be found in a cooperative plan that would assure the farmer of his full share of every cent of profit there might be extracted from the business. To this end it might be advisable to establish a central depot at a convenient shipping point readily accessible to the growers of the district in which the association is formed. To this depot all of the growers would ship all of their potatoes, where they would be inspected and sorted.

"Only those of the very highest quality in every respect would be marketed for seed and table use, and these carefully packed and sold under a name or brand that would establish their reputation. . . . All culls and surplus then could be worked up for industrial purposes, and the volume of supply probably would warrant the erection and operation of the necessary plants for drying, starch manufacturing, and alcohol distilling. The peelings from the dryer

and the residue from it and the starch factory, including the water from the latter, could be used by the distillery for the extraction of all remaining fermentable values. Pulp mash from the distillery and the 'slop' could be returned to the growers for stock food in proportion to their contribution of potatoes or their needs, and all that finally remained returned to the ground for fertilizer.

"In every stage of the operation every pound of potatoes raised might be made to yield a profit to the growers. This presupposes and includes mutual efforts for the improvement in quality and quantity of potatoes grown and for the combating and eradicating of disease. It might be advisable to grow different varieties especially adapted for baking, frying, boiling, and for high starch content."

Suggestions from America for cooperative selling. A. W. ASHBY (*Jour. Bd. Agr. [London]*, 22 (1915), No. 3, pp. 201-210, pl. 1, figs. 2).—This article contains suggestions for British farmers as to methods of marketing their products, and describes successful American cooperative associations, methods of packing and marketing, the use of brands, and advertising.

How farmers cooperate and double profits. C. POE (*New York: Orange Judd Co.*, 1915, pp. 244, pl. 1, fig. 1).—This book discusses cooperation as found in the United States and European countries, describing typical cooperative organizations. The author believes that the success of cooperation depends upon local leadership and loyalty of the cooperators to their organization, and advocates having a farmers' organization in every rural community.

Report of the committee on production of the New York State Food Investigating Commission. 1913 (*Rpt. Com. Prod. N. Y. State Food Invest. Com.*, 1913, Apr. 18, pp. 31).—This report gives detailed statistics concerning the number of farms reporting 1 acre or more of vegetables, with their acreage and value, the cost of producing important vegetables and fruits, and the cost of producing milk in Delaware County for the year 1911-12. For this county it is reported that on 165 farms with 5,164 cows the average cost of keeping a cow was \$122.13, and the average returns \$90.89, making a loss per cow of \$31.24. The report shows details for the different items of expense.

Lower living costs in cities. C. L. KING (*New York and London: D. Appleton & Co.*, 1915, pp. VIII+355).—This book discusses the problem of food distribution from the point of view of the city consumer, and points out defects in the present system and methods that may be used to bring about a more effective and cheaper distribution. He states that the urban prosperity of the future will be dependent upon paying equal heed to the needs, conveniences, and living costs of the urban worker, and that the city should be planned for economic and social efficiency.

Rise of prices in France on account of the war (*Écon. Franç.*, 43 (1915), I, No. 23, pp. 723-725).—In this article is discussed the influence of the war on the price of bread, meat, and other provisions.

Letters from settlers and reports from the seed distribution (*Alaska Stas. Rpt.* 1914, pp. 78-89).—The usual extracts from letters of settlers and other persons, telling of their success with various crops and live stock and describing the possibilities and drawbacks in Alaska, are presented.

Rural survey of Clarke County, Georgia, with special reference to the negroes. W. B. HILL (*Bul. Univ. Ga.*, No. 236 (1915), pp. 63, figs. 19).—There are outlined in this report the physical characteristics of the county, and the economic, educational, religious, and social conditions of its rural population.

Nineteenth biennial report of the Kansas State Board of Agriculture, 1913-14 (*Bien. Rpt. Kans. Bd. Agr.*, 19 (1913-14), pp. VII+1024, pls. 2, figs. 325).—This report contains a number of articles relating to rural schools, churches, social centers, cooperative organizations, farm management, public

Highways, and agricultural education, and statistics relating to crop production and the number of animals by counties.

[Agriculture and rural population in Roumania] (*Bul. Statist. Romaniei*, 3, ser., 12 (1915), No. 36-37, pp. 429-545).—This report shows that of the total population of 7,234,919, 5,904,787 were living in "communes rurales" on December 19, 1912. The increase in the rural population since 1899 amounted to 22.3 per cent. The total area used for agricultural purposes during the crop season 1913-14 was 6,779,009 hectares (16,745,634 acres), of which 4,589,521 hectares were cultivated by farmers with small acreage. The report gives comparative data for earlier years and for minor subdivisions, and for the area devoted to specific crops by the large and small farmers.

[Agriculture in Japan] (*Résumé Statist. Empire Japon*, 29 (1913), pp. 21-32).—These pages of the report give the area cultivated, average and total yield for the principal crops grown in 1913, and comparative data for earlier years.

AGRICULTURAL EDUCATION.

Agricultural education (*Landw. Jahrb. Schweiz*, 28 (1914), No. 3, pp. 235-248).—The development of agricultural education in Switzerland is shown by a historical review beginning with the work of Emanuel v. Feltenberg (1771-1844) and by statistical data.

The statistics show that from 1885 to 1912 the theoretical-practical farm schools with 1-year courses have increased from 3 schools with a total of 130 students and a total state appropriation of \$4,988 to 4 schools with 196 students and \$10,667; the agricultural winter schools, from 1886 to 1912, from 3 schools with 96 students and \$1,507 to 15 schools with 940 students and \$23,916; and 2 dairy schools with 18 students and \$1,986 to 3 schools with 109 students and \$6,506; and the pomological, viticultural, and horticultural schools, from 1887 to 1912, from 1 school with 27 students and \$1,790 to 2 schools with 56 students and \$4,904. The state aid for itinerant lecturers and special courses increased from \$1,603 to \$8,262, and the total state aid for the promotion of agricultural education from \$4,558 to \$56,392.

Alberta schools of agriculture (*Rpt. Demonstr. Farms and Schools Agr. Alberta* [1915], pp. 63-87, figs. 16).—This report outlines the work for the first term just closed of the three schools of agriculture opened in 1913 on demonstration farms at Claresholm, Olds, and Vermilion, and gives a general statement of the results. The attendance for the three schools was 166 boys and 102 girls.

[Reading courses in agriculture and home economics] (*Cornell Reading Courses*, 4 (1914), Nos. 73, pp. 20; 74, pp. 16, figs. 9; 75, pp. 21-44; 76, pp. 17-56, pl. 1, figs. 35; 77, pp. 45-73; 78, pp. 57-72, figs. 7; 4 (1915), Nos. 79, pp. 77-100; 80, pp. 73-100, figs. 27; 81, pp. 101-115; 82, pp. 101-120, figs. 16; 83, pp. 117-139, figs. 4; 84, pp. 121-144, figs. 34).—These reading courses treat of the following subjects: Making cake, introduction to the principles of soil fertility, birds in their relation to agriculture in New York State, songs that live, land drainage and soil efficiency, programs for use in study clubs, incubation, potatoes in the dietary, cream separation, raising vegetables for canning, and insects injurious to the fruit of the apple.

Elementary vocational agriculture for Maryland schools, E. A. MILLEB (*Md. Agr. Col., El. Vocational Agr. for Md. Schools*, 1 (1915), No. 1, pp. 24, figs. 7).—This is the first of a series of publications to be issued, one for each school month, setting forth lessons in elementary vocational agriculture, outlined after a monthly sequence plan and adapted to the seasonal, agricultural, and school conditions of Maryland. This number is devoted to soil, green feed, crops, hog, orchard, vegetable, fruit and flower gardening, and poultry topics.

and management suggestions for September, including in addition to the classroom instruction in underlying principles practical exercises consisting largely of club activities and home projects, suggested correlations, and references to literature.

A uniform course of study in agriculture for the elementary schools of Ohio (*Ohio Dept. Pub. Instr. Bul. 5 (1915), pp. 65*).—This is a suggestive outline of a course in elementary agriculture, arranged in seasonal sequence, for grades 1, 2-4, inclusive, 5 and 6, and 7 and 8, including laboratory and field work, correlations, and references to literature. A price list of agricultural apparatus for a first grade one-room rural elementary school is appended.

Environment of plants.—II, Soils, J. W. HORSON (*Wash. (State) Dept. Ed. Bul. 24 (1914), pp. 62, figs. 9*).—This bulletin for high schools contains exercises intended to illustrate certain phenomena that have been or are occurring in the soil, and is based on 12 years' experience in agricultural teaching.

The home vegetable garden (*Cornell Rural School Leaflet, 8 (1915), No. 4, pp. 337-344, figs. 2*).—This article offers suggestions to the older boys and girls for planning and conducting a home vegetable garden to provide food for the home table.

[Tree study] (*Davey Inst. Tree Survey Instr. Book, 1914, Nos. 1, pp. 16, figs. 7; 2, pp. 16, figs. 5; 3, pp. 16, figs. 11; 4, pp. 24, figs. 18; 5, pp. 31, figs. 18; 6, pp. 19, figs. 26; 7, pp. 24, figs. 17; 8, pp. 28; 9, pp. 24, figs. 2; 10, pp. 32, figs. 12; 11, pp. 40, figs. 13; 12, pp. 24, figs. 19*).—This is a series of lessons devoted to a study of the structure of the tree, agencies which destroy trees, including insects, fungi, and bacteria, and other agencies, with the remedies and preventives, pruning, the use of dynamite in tree culture, correct tree planting, spraying materials and machinery, proper treatment of tree diseases, shade tree insects, and city forestry.

Productive feeding of farm animals, F. W. WOLL, edited by K. C. DAVIS (*Philadelphia: J. B. Lippincott Co., 1915, pp. XI+332, pl. 1, figs. 96*).—This text, prepared for use of agricultural schools and colleges as well as practical farmers, is a systematic treatment of the main principles relating to the feeding of farm animals, and of various feeding stuffs available to stockmen.

Materials for a course in animal husbandry, W. H. SMITH (*School Sci. and Math., 15 (1915), No. 2, pp. 100-104*).—This article contains an outline and a discussion of subject matter and of the use of supplementary materials for a course in animal husbandry in the secondary schools. The author deems it "more advisable to make a detailed study of a few classes of animals common to the community than to touch lightly on many with which the student, perhaps in the course of a lifetime, would never come in contact."

Cattle husbandry in rural education for Georgia schools (*Bul. Univ. Ga., No. 218 (1914), pp. 39, figs. 24*).—This bulletin is not intended as a manual for a detailed course of study, but as an appeal to the historical and economic interests of the pupils and to the home and farm interests centering around cattle husbandry. It discusses the educational, social, and economic importance of the subject, the field and the need of cattle husbandry in Georgia, possibilities for progress, types and breeds of cattle, and Georgia boys' cattle clubs, including score cards for beef and dairy cattle.

Judging of draft horses, W. H. PALMER (*Agr. Col. Ext. Bul. [Ohio State Univ.], 10 (1915), No. 8, pp. 24, figs. 37*).—A study of requirements and relative values for judging draft horses.

Outlines for work in domestic science and domestic arts for the elementary schools in Illinois (*Univ. Ill. Bul., 12 (1915), No. 18, pp. 16*).—These outlines are given for fifth and sixth grade sewing requiring 60 minutes a week and seventh and eighth grade cooking requiring one double period a week. They are

the result of several years of work by the committee of the domestic science section of the Illinois High School Conference.

Home canning of fruits and vegetables, J. C. HOGENSON (*Utah Agr. Col., Ext. Div. Circ.*, 2 (1914), No. 25, pp. 10).—Instructions to girls for the home canning of fruits and vegetables are given.

How to teach birds, F. O. PAYNE (*Chicago: A Flanagan Co.*, 1913, pp. 57, figs. 16).—The author gives an outline of subject matter for the study of birds as a branch of nature study. A list of books helpful to beginners is added.

Outlines in domestic science (*Iowa State Col., Teachers' Short Course Class Notes*, 1914-15, pp. 13).—Lessons in eggs and milk, cereals, meat and meat substitutes, and bread and bread making, are outlined for the use of teachers.

A study of poultry, M. J. ABBEY (*W. Va. School Agr.*, 5 (1914), No. 3, pp. 28, figs. 16).—This bulletin is a guide for the study of poultry raising in the months of November to February, inclusive.

A laboratory guide and notebook for use in the study of food preparation for high-school classes in domestic science, BETH W. MULL (*Topick Kans.: Domestic Science Publishing Co.*, 1914, pp. 160).—The material in this notebook is suggested as the result of several years of experience in teaching and supervising secondary domestic science and each experiment has been tried out in both upper-grade and high-school classes. Only a few recipes are given in the practical application of each experiment to illustrate the possibilities of discoveries made.

Conducting a colt show, W. A. BUCHANAN (*Iowa State Col. Agr. Ext. Bul.* 21 (1914), pp. 12, figs. 4).—The author gives directions for organizing and conducting colt shows.

A successful corn growing contest in Black Hawk County, A. A. BURGER (*Iowa State Col. Agr. Ext. Bul.* 23 (1915), pp. 8, figs. 5).—This bulletin contains an account of the rules, conduct, arrangement of exhibit, judging, and results of an acre-yield corn contest open to every corn grower in Black Hawk County, Iowa.

Profit competitions, W. B. ROADHOUSE (*Agr. Gaz. Canada*, 2 (1915), No. 2, pp. 145-149).—Tables are given showing the results of the acre profit competition and the hog feeding competition carried on by the Ontario Department of Agriculture during the past season. These competitions were open to boys who had taken the six weeks' short course with the district representatives who conducted the contests.

Field crop competitions and seed fairs (*Agr. Gaz. Canada*, 2 (1915), No. 1, pp. 62-72, figs. 3).—This article contains reports of progress of the field crop competition and seed fair movement in Prince Edward Island, New Brunswick, Quebec, Ontario, Manitoba, Saskatchewan, and British Columbia.

Uniform county fair premium lists, R. F. O'DONNELL (*Iowa State Col. Agr. Ext. Bul.* 30 (1915), pp. 12, fig. 1).—The author suggests a uniform classification of horses, cattle, swine, and sheep which can be used in exhibits at all fairs.

Boys' and girls' agricultural clubs (*Timely Helps for Farmers [Col. Agr. Univ. Maine]*, 8 (1915), No. 7, pp. 49-56, fig. 1).—This circular outlines the purpose and results of boys' and girls' club work in Maine, together with the organization of local, general, and state clubs and the county association of agricultural clubs.

Farmers' clubs (*Univ. Minn., Dept. Agr., Ext. Bul.* 56 (1915), pp. 16, figs. 5).—This bulletin reports the progress made by the farmers' club movement in Minnesota and suggests programs for 1915.

The county farm adviser, B. H. CROCHERON (*California Sta. Circ.* 133 (1915), pp. 8, figs. 7).—A revision of Circular 112 (E. S. R., 30, p. 695), describing the work of the farm adviser and how it is organized and conducted.

Annual report of director of extension for the year ending November 1, 1914 (*N. J. Agr. Col. Ext. Bul.*, 1 (1915), No. 1, pp. 16).—This report deals with the farm demonstrations, county work, lectures, correspondence, publications, farmers' week, etc.

Farmers' cooperative demonstration and extension work, W. W. LONG (*Clemson Agr. Col. S. C., Ann. Rpt. Demon. and Ext. Work, 1914*, pp. 63).—This report includes a review of an experiment conducted by J. M. Napier, demonstrator in agricultural education, in teaching agriculture in five rural consolidated schools in Darlington County. Each school was visited twice a week by the demonstrator and has 3 acres devoted to soil-building demonstrations by means of a 3-year rotation and 1 acre to orchard.

Farmers' institute work in the United States in 1914, and notes on agricultural extension work in foreign countries, J. M. STEDMAN (*U. S. Dept. Agr. Bul.* 269 (1915), pp. 21).—This is the annual report of the Farmers' Institute Specialist of the Office of Experiment Stations on the progress of the farmers' institute movement in the various States and Territories for the fiscal year ended June 30, 1914, including a list of the officials in charge of farmers' institute work in the United States and the usual statistical tables covering various lines of institute effort. Notes on agricultural extension work in foreign countries are also given.

MISCELLANEOUS.

Annual Report of Alaska Stations, 1914 (*Alaska Stats. Rpt. 1914*, pp. 96, pls. 12).—This contains the organization list and a report of the several lines of work carried on during the fiscal year ended June 30, 1914. Meteorological data and accounts of the extensive tests with field and garden crops, live-stock operations, and of other lines of work are abstracted elsewhere in this issue.

Annual Report of Nevada Station, 1914 (*Nevada Sta. Rpt. 1914*, pp. 55, pls. 2).—This contains the organization list, a report of the director on the work of the station and including a discussion of a number of problems of experiment station organization and policy, departmental reports, the experimental work in which is for the most part abstracted elsewhere in this issue, a financial statement for the fiscal year ended June 30, 1914, and a list of the publications of the year.

Monthly bulletin of the Western Washington Substation (*Washington Sta., West. Wash. Sta., Mo. Bul.*, 3 (1915), Nos. 4, pp. 8; 5, pp. 16).—These numbers contain brief articles on the following subjects:

Vol. 3, No. 4.—Managing the Bull, by H. L. Blanchard; Summer Care of Strawberries, by J. L. Stahl; Plant Diseases are Prevalent, by H. L. Rees; Late Sown Feed Crops, by E. B. Stookey; and Care of Moulting Hens, by V. R. McBride.

Vol. 3, No. 5.—Agricultural Fairs; Always Hill Select Potato Seed, by H. L. Rees; Preparing for Fall Planting, by E. B. Stookey; Common Errors in Poultry Keeping, by V. R. McBride; The Queen Bee, by J. W. Ware; and A Remedy for Clover Bloat.

Program of work of the United States Department of Agriculture for the fiscal year 1916, E. H. BRADLEY (*Washington: Govt.*, 1915, pp. XXVI+447).—The proposed activities of this Department are set forth in project form.

Laws applicable to the United States Department of Agriculture, compiled by O. H. GATES (*Washington: U. S. Dept. Agr., Office Solicitor, 1915. 3. Sup.*, pp. 71).—This publication represents a revision of that previously noted (*E. S. R.*, 32, p. 693), embracing legislation enacted from October 25, 1914, to March 4, 1915, inclusive.

NOTES.

Arizona University and Station.—Director R. H. Forbes has been granted a year's leave of absence, a part of which will be spent in research at the Graduate School of Agriculture at Riverside, California. During his absence G. F. Freeman, head of the department of plant breeding, has been designated acting dean of the college of agriculture and acting director of the station.

Connecticut College.—Dr. Edmund W. Sinnott, of the Bussey Institution of Harvard University, has been appointed professor of botany and genetics, vice Dr. A. F. Blakeslee whose resignation has been previously noted.

Georgia College.—L. M. Roderick, D. V. M. (Ohio State University, 1915), has been appointed instructor in veterinary medicine.

Hawaii Station.—D. T. Fullaway resigned as entomologist June 30 to become field entomologist of the territorial board of agriculture and forestry. W. T. McGeorge, chemist, was transferred July 7 to the San Francisco branch of the food and drug division of this Department and was succeeded July 25 by Maxwell O. Johnson, transferred from the meat inspection division of the Bureau of Animal Industry. J. B. Thompson, formerly in charge of the Guam Station, was appointed assistant agronomist in charge of the Glenwood substation July 5, succeeding F. A. Clowes, resigned to take charge of the agricultural work at the Lahainaluna School at Lahaina.

Massachusetts College and Station.—Stockbridge Hall, the new agricultural building, is nearing completion. This will be the largest and finest building on the campus, costing with equipment \$210,000. It is a three-story and basement structure, with a fourth floor attic containing a cereal and crop storage room constructed as a mouse-proof vault. The basement contains soil laboratories, a cement laboratory, and several offices, dark rooms, storage rooms, etc. The first floor is largely devoted to offices and lecture rooms and to the auditorium. This auditorium seats about 900, and is bowl-shaped with a stage 22 by 36 feet. The second and third floors contain laboratories, offices, a library, the agricultural museum, etc.

The entering class numbers over 200 and the entire enrollment over 650.

Recent appointments include the following: John Phelan, professor of rural sociology; Andrew S. Thomson, assistant professor of market gardening; Charles H. Thompson, assistant professor of horticulture; Earl Jones, assistant professor of agronomy; O. A. Jamison, assistant professor of dairying; Eric N. Boland, in charge of boys' and girls' pig club work; Paul Serex, Jr., instructor in chemistry, vice Robert H. Bogue, appointed assistant professor of agricultural chemistry in the Montana College; Alfred G. Lunn, extension assistant in poultry husbandry; Arnold P. Sturtevant, assistant in veterinary science in the station for work in bee diseases; F. G. Merkle, assistant in agronomy; R. P. Armstrong, graduate assistant in pomology, vice John B. Norton, resigned July 1; Donald White, graduate assistant in poultry husbandry beginning September 1; and Harold F. Tompson for station work in market gardening.

George F. Story has resigned as extension instructor in animal husbandry to become professor of animal and dairy husbandry in the Vermont University and Station, and J. A. McLean as associate professor of animal husbandry to

engage in commercial work. R. W. Ruprecht, assistant chemist, has been given a year's leave of absence for graduate work at Cornell University.

The veterinary and poultry departments of the station are cooperating with the college extension service in a campaign to eliminate bacillary white diarrhea from the State.

Michigan College and Station.—President J. L. Snyder has been appointed president emeritus, and Dr. F. S. Kedzie acting president. O. F. Jensen has resigned as assistant chemist to pursue graduate studies at the Iowa College. E. J. Miller and E. F. Berger have been appointed assistant chemists.

New Hampshire College and Station.—Charles H. Otis, Ph. D., instructor in botany in the college of arts and sciences of Cornell University, has been appointed assistant in botany and assistant botanist.

Oklahoma College.—Dr. L. Charles Raiford of the department of chemistry of the University of Chicago has been appointed professor of chemistry.

Pennsylvania College and Station.—Work has been started by the experiment station to determine the fertilizer needs of the Dekalb soils, which comprise 43 per cent of the area of the State. A preliminary test, made near Snow Shoe, indicates that abandoned land, as well as virgin soil, responds well to the application of lime. Pot experiments with this soil at the college show that the prime needs are lime and phosphorus. The experiment will be continued and field plats laid off on a larger scale next spring.

R. U. Blasingame resigned August 1 as instructor in agronomy, and A. R. Bechtel as instructor and assistant botanist, September 1. Recent appointments include the following: A. A. Borland as professor of dairy husbandry extension, beginning October 1; Miss M. Jane Newcomb as instructor in home economics extension, beginning September 1; and beginning July 1 A. F. Mason, instructor in horticultural extension, C. W. Clemmer, assistant in agricultural extension, W. D. Swope, assistant in dairy husbandry, F. P. Weaver, transferred from instructor in agricultural chemistry to instructor in farm organization, H. D. Edmiston, transferred from assistant in experimental agricultural chemistry to assistant in agricultural extension, and H. R. Kraybill, transferred from assistant in experimental agricultural chemistry to instructor in agricultural chemistry.

Texas College and Station.—Wilmon Newell, professor of entomology in the college, entomologist in charge of the division of entomology in the station, and ex-officio state entomologist, resigned October 1 to accept a position in Florida under the State Plant Act. The college and station work in entomology have now been separated, and F. B. Paddock has been appointed entomologist in charge of the division of entomology and state entomologist. O. K. Courtney, formerly assistant entomologist in the college, has been appointed assistant entomologist in the station and assistant state entomologist. Louis Wermelskirschen, of the Office of Cereal Investigations of this Department, has been appointed agronomist beginning October 15. H. H. Jobson has been granted two years' leave of absence, beginning November 1, to accept a position as cotton expert with the Chinese Government.

Washington College and Station.—H. W. Reough has been appointed agriculturist of Grant County with headquarters at Ephrata. R. L. Buchanan, assistant in farm crops, has resigned to become county agent with headquarters at Parkersburg, W. Va.

The station has received a donation of \$1,000 from William Anderson, of Winthrop, for use in the investigation of the diseases of domestic animals.

EXPERIMENT STATION RECORD.

VOL. XXXIII.

DECEMBER, 1915.

No. 8.

The recent convention of the International Association of Dairy and Milk Inspectors in Washington, D. C., has directed attention anew to the systematic efforts being made to safeguard on a scientific basis the milk supply of the Nation, and to the remarkable progress achieved in ideals and methods of carrying on this important function. This association, it may be recalled, was organized in 1912 "to develop uniform and efficient inspection of dairy farms, milk establishments, milk, and milk products," but its program has a much wider significance and interest than is attached to technical details of detecting violations of law and conducting prosecutions.

Milk inspection, as was pointed out by a number of speakers at this meeting, has come to be far more than a matter of routine police work. It rests upon a foundation of scientific research in such branches as chemistry, bacteriology, human and veterinary medicine, sanitary science, rural engineering, and economics, as well as of dairying and dairy-farm management. Its aim, also, is not merely regulatory but constructive and educational. This is exemplified in the program of its meetings, the range of subjects including scientific, technical, economic, and educational papers, as well as those dealing with administrative details. Its meetings, therefore, partake of the nature of a national conference of all who are interested in the milk question.

Thus, at the recent Washington meeting, an entire session was devoted to a discussion by Drs. Melvin, Mohler, and Schroeder, of the Bureau of Animal Industry, of problems related to tuberculosis, foot-and-mouth disease, and contagious abortion in dairy cattle. Dr. J. W. Kerr, of the United States Public Health Service, took up the control of milk-borne diseases of man, and Ernest Kelly, of the Dairy Division, the need of medical inspection of employees engaged in the production and handling of milk. There was a technical discussion of the significance of bacteriology in milk by L. A. Rogers, also of the Dairy Division, and a popular address on inspection from the standpoint of the milk and cream producer by Dr. H. W. Wiley, formerly chief of the Bureau of Chemistry.

The work of the agricultural colleges and experiment stations in relation to a better milk supply was a topic assigned to Prof. W. A. Stocking, of the Cornell University and Station. The relations of milk inspection to other forms of food control were outlined by Dr. C. L. Alsberg, chief of the Bureau of Chemistry, who spoke with special reference to the policy of that Bureau in dairy and milk inspection under the Food and Drugs Act; and Dr. John F. Anderson, president of the American Public Health Association, discussed milk standards or grades. The committee reports likewise covered a wide range of subjects, such as bovine and human diseases in their relation to the milk supply and to the public health, dairy farm and city milk plant inspection, the chemical examination of milk and milk products, methods of appointment and compensation of inspectors, and legislation and legislative limits for the control of milk and cream.

This program amply indicates the manifold phases and breadth which this subject has assumed within recent years. From being primarily an examination by rather crude methods to detect watering or skimming, milk inspection has become a far-reaching and many-sided function, involving the health of the animals producing the milk, the sanitary conditions under which it is produced and handled, and the large question of disease transmission, quite as much as the strictly chemical control. All this has developed through and along with investigation, much of it in the field of agricultural investigation.

The response of dairying to the progress of investigation has perhaps been more rapid than that in almost any other branch of agriculture. Here, to a very notable extent, the rule of thumb has given way to the rule of reason, and the progress of the industry has been with and as a result of a clearer understanding. As it has become a more intelligent industry, so it has likewise become a more technical and complicated one, success requiring higher skill and superior judgment, and more attention to the ultimate use of the product.

The relations of the producer and consumer have become increasingly evident as investigation has developed, and this has led to larger reliance upon the inspection service to look after the consumers' interests, and at the same time to instruct the producers. Assistance to the producer has not been overlooked, for success does not flourish under an attitude of antagonism growing out of compulsion, but under one of cooperation. The inspection agencies have thus been a medium of instruction, and the experiment stations and this Department, in their investigations, have had the producer in mind quite as much as the consumer, in order that he might improve his business in producing a better quality of product. This dual rela-

tionship gives to the meeting general agricultural interest, which takes account of the progress in the production of a safe milk supply.

How large and important the question of milk supply has become may be seen from a recent estimate that in 1909 4,260,324,206 gallons of milk were consumed as such in this country. This represented an estimated value to the producer of \$647,569,279, and to the consumer of \$1,463,847,397. The perishable nature of this food and its peculiar susceptibility to contamination and the transmission of infectious diseases, coupled with its extensive use in the feeding of infants and invalids, make manifest the need of adequate systems of inspection.

Efforts to safeguard the milk supply against adulteration began in this country many years ago. In fact, many communities had laws or ordinances for the prevention of milk adulteration long before making any attempt at general regulation of the entire food supply. Probably the first dairy laws were those enacted in Massachusetts in 1856 against the adulteration of milk by adding water, and in 1859 prohibiting the feeding of brewery waste to cattle. During the latter year the appointment of dairy inspectors was authorized, and in 1880 a minimum standard was fixed for total solids in milk.

Much of the earlier legislation, as already pointed out, was directed against the deliberate adulteration of milk, as by watering, skimming, and the addition of preservatives, artificial color, or thickening agents, and was based upon a more or less crude examination of the milk as it appeared in the market. The necessity for inspection of the dairies and of the cattle producing the milk became apparent with the increased knowledge of the sources of milk infection and its dangers, and the sanitary side assumed a prominence fully equal to the chemical and physical. In 1895, a milk law was enacted for the District of Columbia under which permits were required for the sale of milk, and one condition for granting these permits was the maintenance in a sanitary condition of the cattle producing the milk wherever located, as well as of the premises where it was produced and handled. In 1898, the city of Boston adopted somewhat similar ordinances governing the sanitary condition of its milk supply, and since then regulation along these lines has become quite general.

The first attempt to rate conditions on dairy farms in terms of figures was in the District of Columbia in 1904, when Dr. Woodward, of the Health Department, originated a score card for this purpose. In 1905, R. A. Pearson evolved the Cornell score card, and in 1906 a modified score card was issued by the Dairy Division of this Department. In 1907, the Association of Official Dairy In-

structors prepared a card, which has been revised in succeeding years and is now in extensive use.

Practically contemporaneous with the development of the inspection movement has been that of the medical milk commission, which started as a professional crusade in 1889 of the Medical Society of New Jersey, but which united with its sanitarians, health authorities, and other agencies striving for pure milk. The purpose of these commissions, which numbered in 1914 about 75, was primarily the production of what came to be known as "certified milk," but with the organization of the American Association of Medical Milk Commissions in 1907, it took on a wider scope and included an educational propaganda looking toward the betterment of all milk supplies. This movement has had considerable influence in improving the general milk supplies of cities where such commissions exist, by setting a higher standard of quality and by creating a public sentiment in favor of pure milk. In 1910 a commission appointed by the New York Milk Committee advised the establishment of milk standards, with proper labeling. The State of New York subsequently defined grades of milk for sale in cities and villages, and many communities throughout the country have taken similar action.

The change in spirit manifested in the administration of milk inspection regulations was a theme referred to by many of the speakers. Thus, Professor Stocking declared that "formerly the prime object of the inspector was to bring legal action against and impose a penalty upon every man who did not conform to the established ideals. Fortunately, this spirit has given place to one of helpfulness, and the prime object of the inspector now is to assist the producer and handler in so conducting his business that his product will be of the best quality." Similarly, Dr. Alsberg referred to the present day ideal, not of mere prosecution of offenders but of cooperation and constructive work with all concerned. The inspection of milk and dairies has come to be looked upon as less a police than as an educational duty, and the inspector, so far as possible, as an educator and advisor to both producer and consumer.

One result of this change in attitude has been the increased weight attached to the qualifications of the inspector. Whereas a few years ago appointing officials did not always appreciate the importance of this factor, the need of selecting men with thorough scientific training and experience, so far as available, is now becoming more generally recognized. It was pointed out by Professor Stocking that one function of the agricultural colleges is to train men for this line of work.

Even more fundamental is the establishment of a body of scientific knowledge as the foundation for a sound practice. If regulations,

however salutary in purpose, are promulgated without sufficient consideration as to their necessity or practicability, friction in their enforcement is well-nigh inevitable. It is the function of science to forestall the possibility, in the zeal for improvement, of arbitrary requirements and consequent injustice by providing a definite answer as to what conditions are fair and essential.

The experiment stations and the Dairy Division of this Department, as was frequently pointed out at the meeting, have been prominent among the many agencies instrumental in supplying information along these lines. A resolution was adopted by the association endorsing the work of the Dairy Division, and especially that pertaining to its market milk investigations. The stations have not, of course, been directly engaged in enforcing inspection laws, but matters relating to inspection problems have received careful attention, and much of their work has been fundamental. The composition and properties of milk, its cost of production, the effect of various dairy practices on its quality, and many other factors have been studied, and knowledge acquired which has been useful in the drafting and administration of fair and adequate regulations and also in many other ways. For instance, early in the history of the stations, the invention of the Babcock test at the Wisconsin Station in 1890 provided a means of rapidly ascertaining the fat content of milk and cream in place of the former cumbersome and time-consuming extraction methods, and its adoption not only facilitated the campaign against adulteration by skimming but led to far-reaching changes in the whole dairy industry by its intimate relations to herd improvement and similar phases.

It is probable that the stations have also rendered much useful service by dispelling popular prejudice against certain dairy methods and showing that these were unobjectionable. As an example, the introduction of the silo has revolutionized dairy practice in this country, yet for many years there was a strong prejudice on the part of some consumers against milk from cows fed corn silage. The studies of the Wisconsin Station, reported in 1897, and of the Illinois Station reported in 1905 demonstrated that corn silage, fed under proper precautions, did not produce objectionable flavors in milk and its use in high-grade dairies is to-day well-nigh universal.

Another early popular fallacy was that yellow color in milk and cream is indicative of richness in butter fat. Palmer, of the Dairy Division, and Eckles, of the Missouri Station, however, have demonstrated that very little relation exists between the two characteristics, the color being identified as mainly the substance carotin found in certain feeds which, when consumed by cows, imparts its shade to the milk and cream.

The readiness with which milk absorbs odors from the air was early demonstrated by station workers and led to radical reforms in methods of milk production and care. The discovery of the value of the covered and the small-topped milk pail was a consequence of the experiments at the Connecticut Storrs Station and elsewhere, demonstrating that dirt particles and bacteria from the cow's body and the air found their way into the milk. That feeding after milking, washing and clipping the cow's udder and flank, and other aseptic measures all aided in the production of a cleaner and more sanitary milk, was also indicated. The accumulated results of such studies as these pointed to the cow as a leading source of infection and logically led to effective and practical remedies. The importance of prompt and efficient cooling of milk followed studies of the temperature relations of dairy bacteria, and has become a part of good practice. The effect of milking machines on the germ content of the milk has been studied by various institutions, and the necessity of exercising proper precautions, especially in washing and cleansing all parts, has been amply demonstrated through practical trials.

The subject of pasteurization has received no little attention from the Dairy Division and from many station workers. The pasteurization of milk in the bottle has recently been found to be entirely feasible and to be even more efficient in reducing the bacterial content of milk than the customary "holder" system of pasteurizing. The relation of proper pasteurization as an efficient safeguard against the spread of communicable diseases has likewise been shown in both a scientific and a practical way. Aside from the effects of pasteurization in reducing the bacterial content of milk, the influence of heat upon the composition and properties of milk has received attention, notably that upon the viscosity of milk and the proteids and fat globules.

The sources of bacteria in milk have been studied as well as the fermentations produced by various species. Particular attention has been paid to the prevention of bacterial contamination, and methods of destroying or delaying the development of the organisms that do gain access to milk have been repeatedly tested. Much valuable information has been acquired, but as was pointed out by Rogers at this meeting, bacteriology is still a young science with a constantly changing technique and frequent discoveries of unexplored fields. This is illustrated by the experience with the bacterial count as an indicator of pollution. For some years, it has been generally assumed that the bacterial content is a measure of the sanitary quality of milk, and the plate method a measure of the bacteria. Recent tests, however, have indicated in the opinion of Professor Stocking, that "extreme liberality must be used in the interpretation of the plate count,

and that it can be depended on only between wide limits for setting definite bacterial standards until we have a means of determining the germ content of milk with greater accuracy. We look to the experiment stations for help in this problem."

A factor of increasing importance to inspection work considered at the meeting of the association is the medical inspection of dairy employees. In reply to questions sent out by the Bureau of Animal Industry to health officials of cities of populations of 5,000 or over, it was found that cities generally have maintained a very incomplete supervision over the health of employees in places where dairy products are handled. Less than one-half of the 560 cities replying claimed to have laws concerning the control of communicable diseases among employees of places where dairy products were produced, and only 10 per cent required reports from milk producers in the event of the occurrence of disease among these families and employees. It was suggested by speakers at the meeting that if municipalities were to require certificates of inspection from the health authorities of counties from which their milk supply came, and regular reports of the health of all dairy employees, a powerful impetus would be given toward the reduction of milk-borne diseases.

An entire session of the meeting, as already stated, was very properly given to the question of diseases of dairy animals. Ever since the discovery of the relation of human and bovine tuberculosis, this subject, in particular, has been one to which much persistent study has been devoted. It has escaped the consideration of neither the inspector nor the health official, as well as the veterinarian and scientific investigator.

In 1907, the Bureau of Animal Industry began its first systematic cooperation with cattle owners looking toward the eradication of bovine tuberculosis by an educational campaign in and around the District of Columbia. The tuberculin test was made compulsory in the District of Columbia in 1909. At that time 18.87 per cent of the cattle were found tuberculous; the following year 3.2 per cent; and in January, 1915, 1.75 per cent. The results in connection with tests conducted in 1913 revealed the interesting facts in that out of 203 herds of cattle in Virginia and Maryland, under continuous supervision by the Bureau of Animal Industry, 69 formerly tuberculous herds were free from the disease and that in 56 herds where cooperation had been effective during the period of five years, no case of tuberculosis had been found during that period. As outlined by Dr. Melvin at the meeting of the association, it is now purposed to establish a system of cooperation between the Bureau and breeders of pure-bred cattle, state live-stock authorities, and breed-record associations, it being the intention to maintain an official public

record for all pure-bred herds which can be certified as safe herds from which tuberculosis-free cattle may be purchased. It was announced that this proposal has met with favorable replies from cattle breeders and if put in operation will mark a material advance in the campaign for better milk.

In what has been said no attempt has been made to present a comprehensive review of either the history and present status of milk inspection or of the scientific work related thereto. The aim has been rather to indicate some of the principal lines toward which attention is being directed and to point out the dependence of the inspection service on scientific work for the solution of many of its unsolved problems. Some of these problems are, of course, outside the field of experiment station activity, but others appear both appropriate and feasible, and it is thought that their consideration may prove suggestive of opportunities for research at once fundamental and of immediate application.

There are several lessons to be drawn from the history of milk and dairy inspection as developed in the last quarter of a century. One is that safe progress in defining methods and standards must rest upon investigation, which must often be thorough and far-reaching in order to serve as an intelligent basis for action. Nowhere is the danger of imperfect information and too broad generalization more strikingly enforced by possible consequences. The investigation can not safely stop with the empirical fact but needs to disclose the cause and the relationships.

Nor can it be restricted to the laboratory and to laboratory conditions. It is when laboratory studies have been supported by studies and trials on a practical scale and under practical conditions that the results have been most convincing and have proved most dependable. And finally, the investigator must take full account of the producer, in the effort to help him to make his practice more scientific and the science of production more practical.

RECENT WORK IN AGRICULTURAL SCIENCE.

AGRICULTURAL CHEMISTRY—AGROTECHNY.

A study of the soft resins in sulphured and unsulphured hops in cold and in open storage, G. A. RUSSELL (*U. S. Dept. Agr. Bul. 282 (1915), pp. 19, figs. 10*).—The commercial value of hops is almost entirely contingent upon two considerations, viz, the nature and quantity of the soft resins and the aroma. In order to get additional data (*E. S. R., 29, p. 13*) regarding the effect of various storage conditions upon the soft resins of sulphured and unsulphured hops, a quantity of material obtained from Perkins, Cal., was prepared and held under observation for several years.

“Although sulphuring and cold storage are efficient factors in retarding the diminution of the quantity of soft resins in hops, they do not prevent chemical changes from taking place therein. Nevertheless, the data obtained by the study of these changes indicate that they are influenced to a considerable degree by both sulphuring and cold storage. . . .

“Determinations were made of the moisture, the percentage of soft resins, hard resins, and total resins, of the color, odor, and taste of the soft resins, and of the acid, ester, saponification, and iodine values of the soft resins. The moisture content in the sulphured and unsulphured hops held in cold storage increased during the first year and then remained practically constant in all the samples throughout the period of storage. The moisture content of the sulphured and unsulphured hops in open storage varied from year to year, according to existing weather conditions.

“The percentage of soft resins in all the samples decreased with each year of storage, becoming very pronounced in the third year. The percentage of hard resins in all the samples increased with each year of storage, approaching a uniform figure at the close of the third year. Both sulphuring and cold storage retarded the decrease in the percentage of soft resins and increased the percentage of hard resins. A combination of the two factors was more effective in retarding these changes than either factor alone.

“The percentage of total resins in all the samples varied from year to year, and in the third year it became materially less than that of the original sample. The low total is probably due to the formation of products insoluble in the solvents used.

“The color, odor, and taste of the soft resins are of very little value in determining quality and are not indicative of any changes that may have taken place therein.

“The acid value in general decreased in the sulphured hops in cold and in open storage, and increased in the unsulphured hops in cold and in open storage. Sulphuring apparently retards the formation of free acids, and a combination of sulphuring and cold storage is most effective in retarding changes in free acidity.

“The ester value in general increased in all the samples of hops. Sulphuring apparently favors the formation of esters, and this factor in combination with

open storage appears to be the least effective in retarding the formation of esters. Nonsulphuring and open storage appears to be the most effective in retarding the formation of esters.

"The saponification value in general increased in all the samples of hops. The unsulphured hops showed the least change, and of these, the ones held in open storage were the least affected.

"The iodine value in general increased in all the samples. It was most pronounced in the second year of storage and in the third year was uniform in all the samples. Sulphuring in combination with open storage appears to cause a uniform rate of increase in the iodine value from year to year. The sulphured hops in open storage showed the least variation in changes in the chemical values of the soft resins.

"During the period of storage, at least some of the components of the soft resins underwent rearrangement. This rearrangement was most marked during the first year, after which it decreased to such an extent that thereafter comparable values for the chemical constants were readily obtained."

The amount of arsenic in solution when lead arsenate is added to different spray solutions, W. B. ELLETT and J. T. GRISOM (*Virginia Sta. Tech. Bul.* 8 (1915), pp. 160-164; *Rpts.* 1913-14, pp. 160-164).—"Sodium and potassium sulphids dissolve more arsenic when mixed with lead arsenate than the commercial lime and barium sulphur spray solutions. When arsenate of lead is added to either the summer strength of sodium sulphur or potassium sulphur, a large percentage of arsenic goes into solution. Barium chlorid retards the solubility of the arsenic when added to sodium and potassium sulphids.

When lead arsenate is added to the different sulphur spray solutions, the amount of arsenic in solution is increased. This accounts for the burning effect when used together as a spray. . . . If mixtures with arsenic are desired for spraying, lead arsenate is less harmful than Paris green.

"With calcium and barium the arsenic is less soluble than with sodium and potassium. . . . Barium arsenate, when used with the different sulphur sprays, indicates that slight burning would take place with lime and barium sulphur, and that the amount of arsenic in solution is less than when used with water. With sodium and potassium sulphids this substance would be harmful."

Two rapid methods for determining potassium, F. CROTOGINO (*Kali*, 8 (1914), pp. 332-334; *abs. in Ztschr. Angew. Chem.*, 27 (1914), No. 99, *Referatenteil*, p. 697).—The first method is approximate and consists of adding dropwise sodium perchlorate to the potassium chlorid solution until no further precipitation is obtained.

A more exact method is as follows: To 5 cc. of the solution (3.395 gm. in 50 cc.) add 4 cc. sodium perchlorate solution (2,100 gm. in 2,110 cc. of water), rotate, and filter through a weighed filter paper with the aid of the air pump; then wash with alcohol, dry the filter paper and contents at from 135 to 140° C., and weigh. The method requires 15 minutes to carry out. The variation in the results of 35 determinations was 0.23 per cent.

Greiff's method for the volumetric estimation of fluorin, I. BELLUCCI (*Ann. Chem. Appl. [Rome]*, 1 (1914), No. 9-10, pp. 441-446; *abs. in Jour. Chem. Soc. [London]*, 106 (1914), No. 621, II, p. 574).—Tests were made with varying amounts of sodium fluorid in order to ascertain the accuracy and limits of applicability of the method.^a

"The conditions given by this method yield accurate results only when the amount of alkali fluorid does not differ greatly from 0.2 gm.; thus 0.05, 0.04, and 0.02 gm. taken gave, respectively, 0.0449, 0.0336, and 0.0078 gm. found. With

^a Ber. Deut. Chem. Gesell., 46 (1913), No. 12, pp. 2511-2513.

these smaller quantities of fluorids approximate estimations may be effected if the titrations are carried out in the presence of proportionately small amounts of sodium chlorid."

Carbon dioxid apparatus III.—Another special apparatus for the estimation of very minute quantities of carbon dioxid, S. TASHIRO (*Jour. Biol. Chem.*, 16 (1914), No. 4, pp. 485-494, figs. 2).—Although the apparatus previously mentioned (E. S. R., 28, p. 410) is deemed satisfactory for almost all micrometabolic problems, it is sometimes inconvenient for the complete determination of the carbon dioxid production of a single tissue, the metabolic rate of which is constantly changing and the available amount of which is not very great. The device described in this paper was constructed for satisfying this need.

The estimation of nitrogen in Norwegian saltpeter, N. BUSVOLD (*Chem. Ztg.*, 38 (1914), No. 75, pp. 799, 800, fig. 1; *abs. in Ztschr. Angew. Chem.*, 27 (1914), No. 75, *Referatenteil*, p. 545).—It has been found that analyses of Norwegian saltpeter made with the ordinary Kjeldahl apparatus give low results for nitrogen, and a study was therefore made of various other methods. The method finally decided upon was the one utilizing the principle of converting nitrate into ammonia reported by Treadwell and Wegelin.^a

Determination of nitrogen in mixtures of calcium nitrate and cyanamid, A. STUTZER (*Chem. Ztg.*, 38 (1914), No. 56, p. 597; *abs. in Jour. Soc. Chem. Indus.*, 33 (1914), No. 11, p. 606).—In the method nitrite and nitrate are determined first by Schlösing's method (reaction with ferrous chlorid). Then an aliquot made free from nitrate is treated by Kjeldahl's method. "By heating 1 gm. with 5 gm. of dry ferrous chlorid and 25 cc. of concentrated hydrochloric acid, under slight pressure (in a flask fitted with a Bunsen valve), the nitrate may be completely eliminated on the water bath in half an hour. In preparing a mixture of calcium nitrate and cyanamid for use as a fertilizer, loss of nitrogen is liable to occur if the temperature be raised above 60° C."

The vegetation test as a basis for fertilizer analysis, MITSCHERLICH (*Landw. Vers. Stat.*, 85 (1914), No. 3-5, pp. 202-218, figs. 2).—A discussion of the methods for making vegetation tests and their interpretation on a mathematical basis.

The estimation of silicic acid in natural waters, L. W. WINKLER (*Ztschr. Angew. Chem.*, 27 (1914), No. 66-69, *Aufsatzteil*, pp. 511, 512).—The method is based on the yellow color produced when ammonium molybdate is added to a water containing silicic acid and then acidified with hydrochloric acid. The intensity of the color is proportional to the amount of silicic acid present. A solution of potassium dichromate is used as the colorimetric standard.

Note on a new apparatus for use with the Winkler method for dissolved oxygen in water, H. L. SHOUB (*Pub. Health Surv. U. S.*, *Hyg. Lab. Bul.* 96 (1914), pp. 83-85, fig. 1).—A description with illustrations of the apparatus.

Nitrogen-protein table, R. S. CALLAWAY (*Jour. Indus. and Engin. Chem.*, 7 (1915), No. 2, p. 161).—A table for chemists making analyses of feeding stuffs using the factors 5.7 and 6.25.

Apparatus for the determination of fat by the Roese-Gottlieb method, W. BRINSMAID (*Jour. Indus. and Engin. Chem.*, 6 (1914), No. 4, pp. 324, 325, figs. 4).—A modified Roese-Gottlieb tube differing somewhat from the Patrick modification of the apparatus.

The unsaponifiable constituents of natural and hardened fats, J. MARCUSSON and G. MEYERHEIM (*Ztschr. Angew. Chem.*, 27 (1914), No. 28,

^a Kritische Prüfung der wichtigsten Methoden zur Bestimmung der Salpetersäure. Zurich, 1907, pp. 135.

Aufsatzteil, pp. 201-203).—Phytosterol is far more resistant to catalytic reduction than cholesterol. At 200° C. 75 per cent of the latter becomes resinified while phytosterol is hardly affected at this temperature by the catalyst. Hydrogenation at 250° of cholesterol no longer yields crystalline products, whereas appreciable amounts can be obtained from phytosterol under the same conditions. This explains why some of the transformation products of stearins in lard oil are not detected by the examination of the fat. Cholesterol is evidently transformed in a way that will not allow its detection by the digitonin method.

The detection of plant fats in animal fats, H. SPRINKMEYER and A. DIEDRICHS (*Ztschr. Untersuch. Nahr. u. Genussmit.*, 28 (1914), No. 5, pp. 236-244).—The Fritzsche procedure was so modified as to eliminate any possibility of digitonin decomposition products interfering with the melting point determination. When this is not taken into consideration erroneous results may be obtained in regard to the presence of phytosterol in animal fat. The modification was tested on oleomargarin, butter, lard, "premier jus," cotton-seed oil, sesame oil, coconut fat, oleomargarin with 2, 5, and 10 per cent cotton-seed oil, and butter with 10 and 15 per cent coconut fat. The third crystallization usually gave the desired results. Unsatisfactory results were obtained with the method for the detection of 2 per cent cotton-seed oil in oleomargarin, and 10 per cent coconut fat in butter.

The Klostermann method, a modification of the Marcusson and Schilling method (see abstract above), is not deemed as simple nor as cheap to conduct as the Fritzsche modification. A modification of the Klostermann method was studied with lard, "premier jus," oleomargarin, goat tallow, wild hog lard, horse fat, wool fat, whale oil, cotton-seed oil, peanut oil, olive oil, soy-bean oil, linseed oil, poppy-seed oil, corn-seed oil, tea oil, rape-seed oil, niger oil from *Guizota oleifera*, mustard oil, coconut fat, hydrogenated linseed oil, palm fat, cacao butter, Chinese vegetable tallow, Enkabang (Borneo), mowrah butter, shea butter, and mixtures of lard and cotton-seed oil, oleomargarin and cotton-seed oil, wool fat and cotton-seed oil, wool fat and soy-bean oil, wool fat and peanut oil, and oleomargarin and mowrah butter. By this work it was established that cholesterol in animal fats is in the free state, whereas the phytosterol present in plant fats seems to be an ester combination. The lowest melting point was found with the esters of olive oil. The detection of the 2 per cent cotton-seed oil in lard was easily accomplished by this method, but 10 per cent could not be noted, nor could 10 to 15 per cent of peanut oil in wool fat. Ten per cent of soy-bean oil was noted, however. Ten per cent of mowrah fat could not be discovered in oleomargarin. It is concluded that the Klostermann method can in some instances be used in place of the Fritzsche test.

The estimation of carbohydrates.—IV, The presence of free pentoses in plant extracts and the influence of other sugars on their estimation, W. A. DAVIS and G. C. SAWYER (*Jour. Agr. Sci. [England]*, 6 (1914), No. 4, pp. 406-412).—Continuing previous work (E. S. R., 32, p. 314), the present paper brings forth evidence that free pentoses are usually present in alcoholic extracts of plants and have to be taken into consideration in the scheme of analysis. "Their amount can be estimated with a fair degree of accuracy by the ordinary distillation process or by the reducing power of the purified liquor after other sugars have been fermented away. When, however, small amounts of pentose have to be estimated accurately in presence of large quantities of other sugars, it is advisable, as suggested by Kluyver,^a to ferment away these sugars before applying Kröber's process" (E. S. R., 13, p. 320).

^a *Biochemische Suikerbepalingen*. Leyden: E. J. Brill, 1914, pp. XI + 223.

A large number of estimations made with the leaves of different plants (mangolds, turnips, *Tropaeolum majus*, Helianthus, carrot, potato, etc.) showed the percentage of pentose obtained by the distillation method, when applied to the alcoholic extract treated according to the author's scheme of analysis, to range from 0.3 to 1 per cent, calculated on the total vacuum-dried matter. Tests were also carried out with sugars.

In regard to the utility of the Tollens-Krüger method for estimating pentosans, O. FALLADA, E. STEIN, and J. RAVNIKAR (*Österr. Ungar. Ztschr. Zuckerindus. u. Landw.*, 43 (1914), No. 3, pp. 425-432).—Crystalline sucrose submitted to test by the phloroglucin method yielded a higher amount of furfural than previously reported by Andriik.^a This is probably due to the fact that an oil bath with a higher temperature (155° C.) was used in the operation. When the distillations were conducted under uniform conditions, contrary to Andriik's opinion uniform results could be obtained if amounts of 5 gm. sucrose were used for the determination. Above this point ununiformity of results began.

Dextrose and levulose when used in the proportion yielded when 10 gm. of sucrose is hydrolyzed gave 107.4 mg. of phloroglucin, and about the same amounts when treated separately.

Another precipitation method, that of Jager and Unger with babbiturenic acid,^b was also studied. Babbiturenic acid in warm 12 per cent hydrochloric acid yields a condensation product with furfural. In this method the pentosan determination is carried on as in the phloroglucin procedure save that the distillation should be carried quickly to a point of 400 cc. of distillate. The babbiturenic acid yielded lower results for furfural than the phloroglucin method, but it is thought that it should be studied further, as the results obtained with it are deemed more exact.

The present position of the chemistry of starch, H. PRINGSHEIM (*Landw. Vers. Stat.*, 84 (1914), No. 3-4, pp. 267-282).—A digest of the literature.

Determination of calcium in solid substances and fluids derived from the animal organism, S. GUTMANN (*Biochem. Ztschr.*, 58 (1914), No. 6, pp. 470, 471).—In Aron's method (E. S. R., 19, p. 1009) in which the calcium salts are precipitated by alcohol after destruction of the organic matter by a nitric-sulphuric acid mixture, some of the calcium sulphate adheres to the walls of the flask. This error may be obviated if alcohol is added after eliminating the excess of nitric acid and the precipitate is filtered off after standing until the next day. The precipitate thus obtained is returned to the flask and dissolved in a 10 per cent sodium carbonate solution and heated for one-half hour. The carbonate formed is dissolved in acetic acid and the excess of acid neutralized with ammonia, when the calcium is precipitated in the usual manner as calcium oxalate.

A method for determining small amounts of boron in organic materials, G. BERTRAND and H. AGULHON (*Ann. Falsif.*, 7 (1914), No. 67, p. 223).—A correction to the work previously noted (E. S. R., 32, p. 206).

Rapid detection for quantitative estimation of small amounts of esterase, A. BACH (*Fermentforsch.*, 1 (1915), No. 2, pp. 151-154).—Tyrosinase is a mixture of amino acidase and ordinary phenolase. The latter does not oxidize tyrosin as such, but only after it has been converted by amino acidase into paraoxyphenyl acetaldehyde, ammonia, and carbon dioxid. As phenol esters

^a Zeitschr. f. Zuckerindustrie in Pöhhmen. XXXIII, 1898-99, p. 314.

^b Ber. Deut. Chem. Gesell., 35 (1902), No. 20, pp. 4440-4447; 36 (1903), No. 6, pp. 1222-1229.

are not destroyed by phenolase or by peroxidase plus hydrogen peroxid, the following method is employed for noting esterase activity:

One gm. of the material to be tested is rubbed up with quartz sand, and 5 drops of glycerol are incorporated with 500 cc. of lukewarm water and strained through a cloth. Ten cc. of the emulsion-like cloudy fluid is mixed in a test tube with 0.1 gm. of guaiacol carbonate and a few drops of toluol and placed in an incubator at 40° C. At the same time a control test is made under similar conditions but the emulsion added is previously heated to the boiling point. After 5 to 30 minutes both samples are heated rapidly to the boiling point for the purpose of destroying catalase and perhydrase, then cooled, and 1 drop of peroxidase and 1 drop of a 3 per cent solution of hydrogen peroxid are added. According to the quantity of esterases present a more or less brownish red coloration ensues. The control remains colorless.

A method is also given wherewith one can follow the quantitative cleavage of guaiacol carbonate.

International review of the literature of food, its composition, analysis, and adulteration, for the year 1911, A. J. J. VANDEVELDE (*Répert. Internat. Comp., Anal. et Falsif. Deurees Aliment.*, 12 (1911), pp. 88+10).—A continuation of the work previously noted (E. S. R., 29, p. 360).

The decomposition of protein substances of milk through the action of lactic ferments, W. C. DE GRAAFF and MLLÉ. A. SCHAAP (*Ann. Falsif.*, 6 (1913), No. 62, pp. 639-645).—With the aid of the method previously noted (E. S. R., 31, p. 413) it was found that the aldehyde index of buttermilk was much greater than that of fresh milk. This is due to the decomposition of the protein substances of milk by the microscopic flora which develop and cause proteolysis. The cocci and bacilli producing lactic acid are not the only microorganisms which peptonize.

A rapid method for casein in milk, W. O. WALKER (*Jour. Indus. and Engin. Chem.*, 6 (1914), No. 4, p. 356).—An addition to the article noted (E. S. R., 32, p. 413). "Since the above work was completed it has been found that beechwood creosote serves as an admirable preservative for milk. When added in the proportion of 5 cc. to 1 pt. of milk, the latter keeps in good condition for several months if placed in the dark. The preservative does not interfere with the casein test, nor the Babcock fat test, provided only one-half the usual amount of sulphuric acid is used.

The judgment of adulterated milk, R. EICHLOFF and H. BLECKMANN (*Milchw. Zentbl.*, 43 (1914), No. 24, pp. 561-569, fig. 1).—This investigation was conducted for the purpose of determining to what extent the addition of potassium bichromate employed for preserving milk samples affects the specific gravity, total solids, fat-free solids, and percentage of fat.

It is concluded that with milk samples preserved with 0.1 per cent of potassium bichromate the total solids and fat can be determined with accuracy by the gravimetric method. The results obtained with Fleishmann's formula were unsatisfactory, but incorrect results were also obtained in the case of an unpreserved sample.

A balance with which one can make a rapid estimation of total solids is shown and described.

Detecting milk adulteration by the removal of cream, L. VAN DAM (*Ann. Falsif.*, 7 (1914), No. 66, pp. 187-195; *abs. in Ztschr. Angew. Chem.*, 27 (1914), No. 53, *Referatenteil*, p. 417).—It is deemed possible to detect skimmed milk by determining the ratio of casein to fat in the sample. The casein can be determined according to Cornalba's method and the fats according to the Röse-Gottlieb method. In the 144 samples of milk examined the ratio of casein to

fat varied from 0.53 to 0.98, with an average of 0.74. The removal of the cream increased the ratio above 1.

A new constant for detecting partial skimming of milk, R. LEDENT (*Bul. Soc. Chim. Belg.*, 28 (1914), No. 7, pp. 229-234; *abs. in Ztschr. Angew. Chem.*, 27 (1914), No. 99, *Referatenteil*, p. 699).—In this work an attempt was made to bring the ratio of casein to fat as determined by Van Dam (see above) into relation with Cornalba's figures.

The value of the refractometric examination of calcium chlorid serum of milk for the detection of added water, E. ACKERMANN and C. VALENCIEN (*Milchw. Zentbl.*, 43 (1914), No. 13, pp. 345-349).—The views expressed by others as to the value of this method (E. S. R., 18, p. 811) are presented and discussed, and results with 108 samples of composite milk are reported. The data include the fat-free dry substance and refraction. By adding 7 per cent of water to each of the samples the fat-free dry substance was found to vary between 9.19 and 8.63 per cent and the refraction from 38.2 to 37.3 per cent (11 samples 38.2 to 38, and 97 samples 37.9 to 37.3 per cent). The Swiss food book calls for 8.5 per cent fat-free substance.

The refraction of milk serum, L. KISS (*Kisérlet. Közlem.*, 17 (1914), No. 1, pp. 24-34; *abs. in Milchw. Zentbl.*, 43 (1914), No. 18, p. 473).—The refraction of the calcium chlorid serum of milk diluted with water and preserved with formaldehyde or bichromate of potash was studied.

It was found that the refraction of the calcium chlorid serum falls after the milk is diluted with water. For each 1 per cent of water added up to 10 per cent the refraction drops approximately 0.25° . Of the preservatives recommended for keeping milk samples only formaldehyde has an inappreciable influence on the refraction. On the other hand if 0.1 per cent potassium bichromate is employed the refraction rises from 0.3 to 1.1° and with 0.05 per cent potassium bichromate from 0.1 to 0.65° . The calculation of the specific gravity with Wiegner's formula from the refraction of the calcium chlorid serum yielded very good results.

Quévenne's lacto-densimeter and the calculated extract in milk, E. ISNARD (*Ann. Falsif.*, 7 (1914), No. 68, pp. 327, 328).—It is claimed that milk sold as whole milk whose density is less than 1.030 and a skim milk with a density of less than 1.032 must be considered watered.

Society of German Potato Driers (*Ztschr. Angew. Chem.*, 27 (1914), No. 30, *Aufsatzteil*, pp. 278, 279).—This is principally the yearly report of the society, but gives an account of the status of the industry.

METEOROLOGY.

Rainfall and agriculture in the United States, B. C. WALLIS (*Mo. Weather Review*, 43 (1915), No. 6, pp. 267-274, *fig. 1*).—Continuing studies noted in a previous article (E. S. R., 33, p. 318), the author attempts to correlate rainfall conditions and the growth of various crops, particularly wheat, rye, barley, oats, corn, tobacco, and cotton, in the United States.

The results show that the sequence of crops tends to be consistent throughout the country and further indicates that "(1) the wettest month is usually avoided for harvesting operations; generally the harvest is taken in the period following the rainfall maximum. The rainfall maximum of sections G and H [including mainly the east Central States] falls early, so that harvesting may begin in June. In the central Eastern States, however, the harvest tends to be completed before the rainfall maximum occurs. This circumstance is strikingly illustrated in the cotton States, where the cereal harvests are gathered before the heavy rains and the maize and cotton crops after the maximum has passed.

(2) Generally the summer crops are sown almost immediately before the rains commence and the winter and fall crops immediately the heaviest rains are over; the fast-growing crops are well watered at once and the slow-growing seeds lie during a long period which is dry and cold. (3) The variations in the dates of spring sowings are governed by the dates on which the last killing frosts of spring fall due; this is remarkably shown in connection with the sowing of maize (Indian corn). It becomes, therefore, obvious that, while sowing is related to frost as well as to rainfall, there is a definite adjustment of harvesting operations to the rainfall conditions."

It is pointed out that the discussion in this paper is based almost entirely upon average values, and hence the general conclusions are valid only in a broad way. It is stated that attention is concentrated upon rainfall "for the definite purpose of determining the importance of the rainfall factor in the complex conditions of the environment of the agriculturist. In itself the rainfall régime of an area is typical of its latitude, its situation both on the continent and in relation to the ocean. Therefore, a close relationship between successful agriculture and definite rainfall conditions might have been assumed."

The effect of weather upon the yield of potatoes, J. W. SMITH (*Mo. Weather Rev.*, 43 (1915), No. 5, pp. 222-236, figs. 23).—This article discusses the temperature and moisture requirements of potatoes and attempts to correlate the rainfall and temperature of periods of varying lengths during the growing season with the yield of potatoes in central Ohio. Among the conclusions reached are "that cool and wet weather during the first 10 days of July is quite essential as far as central Ohio is concerned, and that the weather of this short period has a large influence upon the final yield of potatoes."

The hottest region in the United States, G. H. WILLSON (*Mo. Weather Rev.*, 43 (1915), No. 6, pp. 278-280).—It is stated "that not only the highest temperature in this country occurred in Death Valley, but that the highest shade temperature ever recorded in the open air with standard instruments and under approved methods of exposure in any portion of the world was recorded at Greenland ranch, on the edge of Death Valley, Inyo County, Cal., on July 10, 1913, when the thermometer registered 134° F."

The region of greatest snowfall in the United States, A. H. PALMER (*Mo. Weather Rev.*, 43 (1915), No. 5, pp. 217-221, pls. 2, fig. 1).—It is shown that the region of greatest snowfall in the United States is that surrounding Tamarack, Alpine County, Cal., where an average season snowfall of 521.3 in. is recorded. Data for distribution of rainfall and snowfall for other places in California are given. Methods and apparatus used in the measurement of snow are described and conditions accompanying heavy snowfall, pressure from snowfall, the economic importance of deep snows, especially with regard to railway traffic, and historical influences of snowfall are discussed.

It is shown that up to a certain height there is an increase in the total annual precipitation with increase of elevation. Forty years' observations along the Southern Pacific Railway show that up to a height of 6,500 ft. there is an average increase of 0.9 in. of rainfall with every 100 ft. increase of elevation, the rate of increase being greatest between the 3,000 and 4,000 ft. levels. Beyond the 6,500-ft. level the precipitation decreases.

The fertilizing value of rain and snow, F. T. SHUTT (*Canada Expt. Farms Rpts.* 1914, pp. 89, 127-129).—The studies here reported have already been noted from another source (*E. S. R.*, 32, p. 615).

Monthly Weather Review (*Mo. Weather Rev.*, 43 (1915), Nos. 5, pp. 211-260, pls. 11, figs. 25; 6, pp. 261-310, pls. 12, figs. 7).—In addition to weather forecasts, river and flood observations and seismological reports for May and June, 1915, lists of additions to the Weather Bureau library and of recent papers

on meteorology and seismology, notes on the weather of the months, a condensed climatological summary, and the usual climatological tables and charts, these numbers contain the following articles:

No. 5.—Solar and Sky Radiation Measured at Washington, D. C., during May, 1915, by H. H. Kimball; Confirmatory Experiments on the Value of the Solar Constant of Radiation, by C. G. Abbot, F. E. Fowle, and L. B. Aldrich; Solar Halo of May 11, 1915, at Sand Key, Fla. (illus.), by C. G. Andrus; Solar Halo of May 20, 1915, at Philadelphia (illus.); Halo of May 20, 1915, at New Haven, Conn., by C. S. Hastings; The Region of Greatest Snowfall in the United States (illus.), by A. H. Palmer (see p. 716); The Effect of Weather upon the Yield of Potatoes (illus.), by J. W. Smith (see p. 716); and Ice Conditions in Danish Waters, A. D. 690-1860.

No. 6.—Solar and Sky Radiation Measured at Washington, D. C., during June, 1915, by H. H. Kimball; Systematic Observation of Meteors, by S. A. Mitchell; Internal Reflection as a Source of Error in the Callendar Bolometric Sunshine Receiver (illus.), by E. R. Miller; Rainfall and Agriculture in the United States (illus.), by B. C. Wallis (see p. 715); A Revolving Cloud Camera (illus.), O. L. Fassig; A Test for Personal Error in Meteorological Observations (illus.), by E. R. Miller; The Hottest Region in the United States, by G. H. Willson (see p. 716); Summer Temperatures at Paris and at Reno, Nev., by H. F. Alciatore; Weather and Radium Emanation at Manila, P. I.; Meteorological Papers Presented at the Havre Meeting of the French Association; The Green Flash at Sunset, by A. W. Porter; and Pernter and Exner on the Green Flash.

Meteorological observations at the Massachusetts Agricultural Experiment Station, J. E. OSTRANDER and D. POTTER (*Massachusetts Sta. Met. Buls.* 319, 320 (1915), pp. 4 each).—Summaries of observations at Amherst, Mass., on pressure, temperature, humidity, precipitation, wind, sunshine, cloudiness, and casual phenomena during July and August, 1915, are presented. The data are briefly discussed in general notes on the weather of each month.

Meteorological records for 1913 and 1914, H. L. PRICE (*Virginia Sta. Tech. Bul.* 8 (1915), pp. 165-169; *Rpts.* 1913-14, pp. 165-169).—Detailed records of tridaily thermometer readings and summaries of observations on temperature, precipitation, cloudiness, and wind for each month of 1913 and 1914 are given.

The United States Weather Bureau, H. E. WILLIAMS (*U. S. Dept. Agr., Weather Bur. [Pamphlet], 1915, pp. 58, figs. 10*).—A brief historical account of the Weather Bureau is given and the nature and value of its work are concisely explained.

SOILS—FERTILIZERS.

The development of the study of soils from its beginning to the twentieth century, O. NEUSS (*Internat. Mitt. Bodenk.*, 4 (1914), No. 6, pp. 453-495).—The author presents a brief historical review covering certain of the more important phases of the development of the study of soils from the time of the early Greeks and Romans.

McLean County soils, C. G. HOPKINS, J. G. MOSIER, E. VAN ALSTINE, and F. W. GARRET (*Illinois Sta. Soil Rpt.* 10 (1915), pp. 52, pls. 4, figs. 8).—This is the tenth of the series of the Illinois county soil reports.

McLean County lies in central Illinois in the early Wisconsin glaciation. The general topography is undulating to slightly rolling. The soils of the county are divided into four classes as follows: (1) Upland prairie soils, rich in organic matter, (2) upland timber soils containing much less organic matter, (3) terrace soils, and (4) swamp and bottom lands. The brown silt loam of the upland

prairie soil occupies 72.6 per cent of the area of the county, the black clay loam of the same class 14.5 per cent, and the yellow-gray silt loam of the upland timber soils 6.2 per cent. It is emphasized that the supplies of plant food in these soils are extremely limited when measured by the needs of large crop yields. "The most significant facts revealed by the investigation of the McLean County soils are the lack of limestone and the low phosphorous content of the common prairie soil and of the most extensive timber type."

Nova Scotia soils, F. T. SHUTT (*Canada Expt. Farms Rpts. 1914, pp. 91-96*).—Physical and chemical analyses of eleven samples of typical soils of Nova Scotia are reported.

The distribution of the climatic soil types in Germany, H. STREMMER (In *Branca Festschrift. Berlin: Bornträger Bros., 1914, p. 16; abs. in Zentbl. Agr. Chem., 44 (1915), No. 1, p. 6*).—Comparative studies of the existing soil types of Germany are reported.

There occur in Germany, in addition to the excessively wet swamp and moor soils, podzol and related soils of medium dampness and black soils of only moderate dampness. The swampy soils generally occur where the annual rainfall exceeds 23 or 24 in., while the podzol and black soils occur in regions having an annual rainfall of less than about 20 in. Chernozem soils occur in the far inland regions south of Breslau and Halle and podzol and related types in Pomerania in the neighborhood of the Baltic. In the podzol soil regions the humus lime soils (rendzine) from the limestone mountains are known to be endodynamorphic soils, as noted by Glinka (*E. S. R., 31, p. 719*). Such soils with the iron horizon very evident, just beginning, and entirely absent are described. Certain so-called black soils in East and West Prussia and other localities, which occur as moor marl in basin formations, are said to be partly humus lime soils. In Schleswig and west and south Germany the characteristic formation of the present soil types is obliterated by fossil soils.

The material carried by the streams of the Alps and the Pyrenees, A. MÜNTZ and E. LAINÉ (*Compt. Rend. Acad. Sci. [Paris], 156 (1913), No. 11, pp. 848-851*).—In connection with investigations of the water resources of the Alps and Pyrenees mountains with reference to the possibilities for irrigation and water power development, studies were made of the silt carried by the streams and of their silt transporting capacities to determine the possibilities of silting of canals and reservoirs. Fifteen observation stations were established in the Alps and eight in the Pyrenees.

The results show that the streams of the Alps carry much more silt and matter in solution than the Pyrenees' streams. The Alps' streams, while relatively clear in the winter, are subject to extreme floods during the spring and summer, at which times they carry enormous quantities of silt. They also carry large and variable amounts of lime in solution at different seasons, these being greatest in the winter when the water is low and clear and least in spring and summer. The streams of the Pyrenees, in which glaciers are practically absent, are relatively clear the year around and carry silt in appreciable quantities only during occasional floods due to heavy rains. The proportion of dissolved matter, principally lime, is much less in these waters than in the Alps' waters and is not subject to such wide variations.

The abundant carrying of material by the streams of the Alps is attributed to the comparatively recent formation of these mountains. The Pyrenees, on the other hand, are of much more ancient formation and have undergone washing an infinitely longer time, so that their streams are clearer.

The importance of the results from the standpoint of the construction of dams, canals, and reservoirs is pointed out.

Studies on the formation of silt and its transportation by streams in the Alps and Pyrenees, A. MÜNTZ and E. LAINÉ (*Compt. Rend. Acad. Sci. [Paris]*, 160 (1915), No. 15, pp. 462-467).—Further studies on the character and amount of the silty material carried by streams in the Alps and Pyrenees confirmed the results noted in the above report.

It was found that the quantities of soluble matter and matter carried in suspension by the streams are extremely variable according to the geological origin of the formations which are drained by them. Ancient formations, consisting mostly of rocks, yield little silt, while recent formations yield relatively more silt. Erosion is, therefore, greater in the Alps than in the Pyrenees.

Analyses of water from the more important streams with reference to the content of suspended matter and matter in solution showed that where the latter is large the former is frequently much larger. Mechanical analyses of silts showed the close relation of the physical composition of the suspended and deposited silt to the velocity of the stream.

Observations on irrigation canals in the Alps region showed that at a velocity of about 5 ft. per second, the sand grains deposited were between about 0.0039 and 0.0097 in. in diameter. With a velocity of about 2½ ft. per second the sand grains were between about 0.00195 and 0.003 in. in diameter, while with a current about 1½ ft. per second, the diameter of the silt particles deposited was less than 0.001 in. The matter remaining in suspension consists, therefore, of the finest particles.

It is pointed out from these results that the mountain waters, particularly those of the Alps, when used for irrigation will deposit an appreciable layer of silt on the land, the grains of which will vary in size from coarse to fine as the streams approach the plains and the grades and velocities diminish.

Studies as to the agricultural value of these deposits are in progress.

Physical and chemical conditions of cultivated and forest soils, A. PAROZZANI (*Ann. R. Staz. Sper. Agrum. e Frutticol. Acireale*, 2 (1914), pp. 23-46).—The views of others with reference to the physical and chemical properties of forest soils are briefly presented, and studies of the changes produced in the physical and chemical properties of forest soils by deforestation and cultivation are reported.

Little difference was, on the whole, observed between the nitrogen content of the forested and deforested soils. The total nitrogen content of forested soils was highest in soils partially cultivated and supporting olive and chestnut trees, and lowest in typical forest soils supporting oak and beech trees. In the oak soils the total nitrogen increased in the surface soil as the closeness of texture decreased, while the opposite was true for the subsoil. In the deforested soils the total nitrogen content was always high in those lying fallow, and especially low in those planted to beans.

The ammonia content of dense cork-oak soils was greater and the nitrate content less than in medium or loose soils of the same type. Of the deforested soils, those lying fallow contained the most ammonia. The deforested soils, in general, contained more nitrate than the forested soils, although the subsoil of olive soils contained more nitrate than deforested cultivated soils. There were more nitrates in the surface soil of the forested soils than in the subsoil.

The cultivated soils had a greater absorbing power, especially for potash, than the forested soils. The water-soluble matter in the cork-oak soils decreased as the looseness in texture increased. The total soluble matter in forested soils, especially in the surface soil, was increased after oxidation with hydrogen peroxid. The same was true for the subsoil of recently deforested soils, except fallow soil.

It is concluded that as regards the difference between forested and cultivated soils in absorbing power, concentration of soil solution, and content of easily oxidizable organic matter, the forested soil represents a state of continuous chemical and physical evolution and is profoundly modified when it reaches the cultivated condition.

A list of references to related literature is appended.

Nitrogen in forest soils, A. PARROZZANI (*Ann. R. Staz. Sper. Agrum. e Frutticol. Acireale*, 2 (1914), pp. 14-22).—After presenting the views of others as to the forms of nitrogen occurring in forest soils, the results of mechanical and chemical analyses of soils from two forests growing beech, common and cork oak, and chestnut trees and broom (*Genista aetnensis*) are reported.

Nitrates were found in all of the soils, except those growing broom, and showed no relation to lime content. Deep soils contained more nitrates than shallow soils. More nitrates were found in the oak soils than in the soils growing other trees and were more evident in the surface than in the subsoil, especially in soils of medium and loose texture. Five soils were rich in nitrates and two were not. Under identical conditions the nitrite content of the oak soils was superior to that of the chestnut and beech soils.

A list of references to literature bearing on the subject is appended.

Correlation between humus and mineral matter in dark colored soils, A. A. BLAGONRAVOV (*Abs. in Zhur. Opytn. Agron. (Russ. Jour. Expt. Landw.)*, 14 (1913), No. 5, pp. 457, 458).—Assuming that degraded dark colored soils have been at one time less degraded and comparing their chemical composition by calculating the percentage composition of the zeolitic portion, the author finds that the changes in the mineral part of these soils correspond with the changes of the humus content. On this basis, and assuming that the lime is carried from the higher horizons downward in the form of calcium crenate, he calculates a series of "simple correlations" between the lime and crenic acid, for which he takes Mulder's formula $C_{24}H_{24}O_{16}$.

With the aid of these correlations it is considered possible, from the difference in the humus of any two soils and the amount of lime in one, to calculate the contents of the zeolitic lime in the other. The values so calculated differ from those found by actual analysis only in hundredths of one per cent. Other constituents of the zeolitic portion are also found by means of calculations from a whole series of ratios. On the basis of correlations between different elements so obtained the difference in the composition of two soils is expressed in the form of formulas by the aid of which, having previously determined the lime percentage, the contents of all the other constituents are calculated. Then accepting for humic acid Detmer's formula $C_{60}H_{54}O_{27}$, the ratios to humic acid of the various bases soluble in 10 per cent hydrochloric acid are found and from these ratios, guided again by the relation between humus and lime (1:4), a formula is deduced for the composition of the mineral constituents of a given soil.

In conclusion, the author reduces the soils of different regions to a small number of groups, being guided by the ratio of the amount of carbon in the humus to the sum of mineral substances (from 10 per cent hydrochloric acid solution).

Bacteria of frozen soil, III, H. J. CONN (*Centbl. Bakt. [etc.]*, 2. Abt., 42 (1914), No. 17-18, pp. 510-519, figs. 3).—Further studies on the subject (E. S. R., 26, p. 520) confirm the former conclusion that the number of bacteria in frozen soil is generally higher than in unfrozen soil. This was true not only of cropped soil but also of sod and fallow soil. Other results of these studies have been reported by the author in bulletin form (E. S. R., 32, p. 33).

The effect of green manuring on soil nitrates under greenhouse conditions, H. H. HILL ET AL. (*Virginia Sta. Tech. Bul. 6* (1915), pp. 121-153; *Rpts. 1913-14*, pp. 121-153).—Pot and laboratory experiments to determine the effect of green manures on nitrate accumulation and plant growth in 5 types of Virginia soils are reported.

Preliminary experiments on the effect of vegetable matter on nitrate formation in partially sterilized and unsterilized silt loam showed that organic matter such as blue grass, clover, and alfalfa when turned under in the soil appeared to pass over into nitrates, more especially in sterilized soil.

In further experiments with soils ranging in texture from sandy loams to heavy clays to which green manures and organic matter were added in the following proportions: 0.3 per cent Swedish filter paper, 0.6 per cent straw, 0.41 per cent clover, 0.44 per cent soy beans, and 0.22 per cent blue grass, it was found that the total number of bacteria in soils treated with green manures was much greater than in soils receiving no green-manure treatment. Legumes gave in most cases the highest bacterial count. The rate of nitrate formation and plant growth in every case was greatly improved by the addition of green manures. There was a smaller amount of nitrogen in plants grown in pots treated with paper than with those grown on untreated soil. Paper in each soil type caused a depression in the number of bacteria, nitrate formation, and in plant growth, and produced a yellow appearance in the plants.

"Soils vary in their power to accumulate nitrogen. Soils, from the same field, when taken at different times, show a variation in nitrogen-accumulating power." "It is believed from the results of this paper that the open soils have a natural tendency toward nitrate accumulation and that this may be stimulated by applications of green materials."

A bibliography is appended.

Some common misconceptions with respect to soils and soil fertility, C. B. LIPMAN (*Mo. Bul. Com. Hort. Cal., 4* (1915), No. 5-6, pp. 231-239).—In an attempt to correct certain of what are considered to be misconceptions with reference to soils and soil fertility, it is pointed out that in the light of present knowledge overirrigation is injurious to crop growth, that analysis of soils is not a criterion for their adaptability to crops or fertilizer needs, and that plant-food elements in fertilizers do not have many of the specific effects on plant growth commonly attributed to them.

The teachings of the Kentucky Agricultural Experiment Station relative to soil fertility, G. ROBERTS (*Kentucky Sta. Bul. 191* (1915), pp. 31-56).—This bulletin, with an introduction by J. H. Kastle, is a general statement of the principles of soil fertility as taught by the station. These are based in part on a previous bulletin (E. S. R., 21, p. 316) and in part on the general results of two, four, and six year series of plat and field experiments in different parts of the State with various field crops to determine the fertility requirements of representative soil types, with particular reference to phosphorus, nitrogen, and potash, and the most effective and economical methods of supplying these when needed. The detailed results of these experiments are to be published in a later publication.

It is the belief that practically all the soils of Kentucky contain inexhaustible supplies of potash, which can be made available with sufficient rapidity through maintenance of the humus content. With the exception of the soils of the blue-grass regions, the soils of the State are considered to be deficient in phosphorus, which usually can be most advantageously supplied as acid phosphate until organic matter is restored to the soil, after which rock phosphate may be used. The purchase of nitrogenous fertilizers is considered uneconomical, nitrogen

being best returned to the soil as farm manure and by the cultivation of legumes and the use of catch crops, cover crops, and crop residues. The general use of complete fertilizers is not considered economical or conducive to a condition of permanent soil fertility. It is recommended that systems of cropping be followed whereby plant food is returned to the soil through crop residues and manures, that rotations containing leguminous and cover crops be used, and that deficiencies in any plant-food element, as indicated by field experiments or chemical analyses, be supplied in the cheapest available form and in quantities sufficient to meet the requirements of a number of crops.

Barnyard manure, P. H. MOORE (*Canada Expt. Farms Rpts. 1914*, pp. 291, 292).—Comparative tests of a mixture of commercial fertilizer alone and the same mixture together with 16 tons of barnyard manure per acre for mangels showed that the plot receiving the second mixture yielded over 3 tons per acre more than the plot receiving the first mixture.

Experiments comparing spring application with winter application of fresh manure, and spring application of manure stacked in the field during the winter with winter application of fresh manure, favored the spring application in both cases.

The losses and preservation of barnyard manure, O. B. WINTER (*Michigan Sta. Circ. 26 (1915)*, pp. 2-8).—This circular calls attention to the losses of plant food in barnyard manure under present systems of farm management and describes methods for its preservation.

The effect of fineness of peat litter on its absorptive power for water, H. VON FEILITZEN (*Mitt. Ver. Förd. Moorkultur Deut. Reiche, 33 (1915)*, No. 6, pp. 85-91, fig. 1).—The work of others bearing on the subject is briefly reviewed and experiments with peat litter and peat dust of various kinds, with reference to their absorptive power for water, are reported. In addition to measuring the size of grains the different samples were subjected to botanical analysis.

It was found that the absorptive power for water increased with fineness of grain until a fineness of from 1 to 2 mm. was reached, after which the absorptive power gradually decreased until a fineness of 0.5 mm. was reached, and then rapidly decreased. The botanical investigation showed that the accessory plant constituents other than sphagnum, which has a much greater absorptive power for water than the others, tend to collect in the finest grains. It is concluded, therefore, that the different absorptive powers for water of the different fine particles of peat dust depend not only on the degree of fineness but perhaps more on the frequent occurrence of accessory plant constituents and humus particles.

The importance of micaceous minerals in agriculture, E. BLANCK (*Fühling's Landw. Ztg., 64 (1915)*, No. 1, pp. 20-28).—The author briefly reviews recent work by himself (E. S. R., 27, p. 520; 29, p. 215) and others which shows that the potassium of biotite is more available as plant food than that of feldspar and much more available than that of muscovite. Experiments by Atterberg (E. S. R., 30, p. 214) are referred to as indicating also that biotite plays a special rôle in connection with the physical properties of certain stiff clays, particularly in increasing their plasticity.

The comparative value of different sources of phosphorus, B. L. HARTWELL and S. C. DAMON (*Rhode Island Sta. Bul. 163 (1915)*, pp. 515-560, pls. 2).—This bulletin reports the unpublished results and a summary of published results of twenty years' continuous field experiments on silt-loam soil composed of glacial drift of granitic origin to compare different phosphatic materials.

Three experiments were conducted. The first was a six-year comparison of Chinchua and Lobos guanós, ground bone, and dissolved phosphate rock so applied as to furnish the same amount of phosphorus, the nitrogen and potas-

sium of the guanos being matched by using nitrate of soda and muriate of potash to supplement the bone and dissolved phosphate rock. The soil was acid. It was found under these conditions that the phosphorus of ground bone was the most available, followed in order by that of guanos and the dissolved phosphate rock. In the second experiment the results of a seven-year comparison of Thomas slag phosphate, Lobos guano, ground bone, and dissolved phosphate rock on an equal phosphorus basis in the presence of liberal amounts of nitrogen and potassium were inconclusive.

The third experiment covered twenty years, the purpose being to determine the relative availability of the phosphorus in dissolved boneblack, dissolved bone, dissolved phosphate rock, fine ground bone, Thomas slag phosphate, raw rock phosphate, raw Redonda phosphate, roasted Redonda phosphate, and double superphosphate applied during the first half of the experiment, with liberal amounts of nitrate of soda and muriate of potash, to limed and unlimed land. In the first five years of the experiment, during which the phosphates were added on the basis of equal cost, it was found that Thomas slag phosphate and ground bone were superior even to dissolved boneblack and dissolved bone on unlimed soil, the reverse being true on limed soil. Dissolved phosphate rock ranked fifth in both the limed and unlimed soil, being markedly superior to the raw phosphate rock. In the following ten years, during which the combined phosphatic applications were adjusted to an equal phosphorus basis, it was found that the most available phosphorus for both limed and unlimed soils was apparently that in Thomas slag phosphate, ground bone, and dissolved bone. The dissolved boneblack and dissolved phosphate rock ranked next and were considerably superior to raw rock phosphate.

The final summary of the entire 20 years' work shows that the after effects of the phosphates were very marked and indicate the importance of continued tenure of the land. The rank of the different phosphates was left practically unchanged with the unlimed plats. With the limed plats the main change was that the dissolved boneblack was placed among those of first rank. Dissolved phosphate rock held an intermediate place, being decidedly superior to double superphosphate, raw rock phosphate, and Redonda phosphate on both limed and unlimed soil. The double superphosphate needed considerable lime for its greatest efficiency, for only on the limed soil did it rank next to the dissolved phosphate rock, being decidedly inferior even to the raw phosphate rock in case of the unlimed soil. With the limed soil roasted Redonda phosphate was somewhat superior to the raw phosphate rock, although decidedly inferior with the unlimed soil. The raw Redonda phosphate was practically valueless.

In connection with this experiment a comparison of the effect of 3 tons of slaked lime per acre applied to the limed phosphate plats with the effect on limed plats receiving no phosphorus showed that in the latter case the increase in the value of the crop during the twenty years, due to the lime, was about \$400 per acre. With the insoluble phosphates, ground bone, Thomas slag phosphate, raw phosphate rock, and raw Redonda phosphate it was \$330 and less, and with the other phosphates the increase ranged from \$442 with the dissolved phosphate rock to \$590 with the double superphosphate.

Use of lime on the farm, C. B. WILLIAMS (*North Carolina Sta. Circ. 28 (1915), pp. 7*).—This circular gives instructions as to the proper use of lime on North Carolina soils and a brief résumé of results secured with lime when used on various crops at the different experimental farms in the State.

Fertilizing materials, F. T. SHUTT (*Canada Expt. Farms Rpts. 1914, pp. 96-104*).—Chemical analyses of 25 samples of marl and limestone, superphosphate of lime, wood ashes, sewage sludge, flue ashes, and pulp mill refuse are reported.

Commercial fertilizers, J. T. WILLARD ET AL. (*Kansas Sta. Bul.* 204 (1915), pp. 3-40).—This bulletin contains actual and guaranteed analyses of 105 samples of fertilizers and fertilizing materials offered for sale in Kansas and a statement of receipts and expenditures from January 1, 1913, to June 30, 1914. On the basis of this inspection the fertilizer business of the State is considered to be in good condition.

There is also a special article by C. O. Swanson on the value and use of fertilizers designed to assist the farmers of Kansas in the intelligent use of fertilizers. It is thought probable that owing to the uncertainty regarding the climate, the tendency in Kansas will be toward the use of more slowly available plant food rather than that which is more quickly available.

A list of Kansas dealers in fertilizers is appended.

Analyses of commercial fertilizers, P. H. WESSELS ET AL. (*Rhode Island Sta. Insp. Bul.*, 1915, July, pp. 8).—This contains actual and guaranteed analyses and valuations of 45 samples of fertilizers and fertilizing materials for sale in Rhode Island in the spring of 1915.

AGRICULTURAL BOTANY.

Plant anatomy, W. I. PALLADIN, trans. by S. TSCHULOK (*Pflanzenanatomie. Leipzig: B. G. Teubner, 1914, pp. IV+195, figs. 174*).—This is a translation of the fifth Russian edition. The three main divisions deal in more or less detail with the anatomy of plant cells, tissues, and organs, and modifications thereof by various agencies. It is designed for use by students of pharmacy, forestry, agriculture, and natural science.

Anatomical relations of some variegated foliage leaves, R. KŌKETSU (*Bot. Mag. [Tokyo]*, 28 (1914), No. 336, pp. 323-325).—The author gives briefly the results of studies carried out with several species of variegated plants.

Green coloring matter is deficient or absent in all or certain layers of variegated leaf parts. The color of such portions depends more or less upon the subepidermal air bubbles or spaces. Cells of such tissue are usually tenderer and smaller than in tissue of normal color, the colorless portions of leaves being also abnormally thin. Tissue differentiation in the mesophyll is usually indistinct or abnormal, intercellular spaces being often abnormally large or small. Starch is absent in the colorless cells. Colorless leaf cells usually contain considerable calcium oxalate, but no oil droplets. Cuticle develops in these cells much as in normal leaves. Stomata are usually about as numerous in these areas as elsewhere, but *Quercus glauca moustrosa* appears to have no stomata in the white portions. Nitrogen and fats are only sparingly present, but sugar is often plentiful. Oxidation enzymes are not abundant.

Some observations are also given in regard to coloration and anatomical correlations in these variegated portions.

Structure and function in contractile roots, G. CATALANO (*Nuovo Gior. Bot. Ital.*, 22 (1915), No. 1, pp. 148-174, figs. 6).—This is an account of anatomical and morphological studies on several plants whose roots show a tendency to more or less persistent shortening and thickening, as related to the storing of reserve material, to moisture as causing more or less temporary turgor, and to other conditions.

The track of stimulus in *Mimosa pudica*, K. LINSBAUER (*Ber. Deut. Bot. Gesell.*, 32 (1914), No. 9, pp. 609-621, figs. 3).—The author cites experiments and observations which are considered to show that the conduction of wound stimulus in *M. pudica* may occur in connection with considerable tracts of the woody portions of the stem, without reference to the presence or absence of the cortex.

Recent studies on mitochondria in vegetable cells, E. CARANO (*Ann. Bot. [Rome]*, 12 (1914), No. 2, pp. 209-217).—This is a synthetic review of recent articles by several authors, appearing from 1911 to 1913.

The rôle of chlorin in plant nutrition, W. E. TOTTINGHAM (*Abs. in Science, n. ser.*, 42 (1915), No. 1071, p. 68).—As the result of investigations the author reports that water cultures of various plants have shown marked stimulative effects of chlorids on root development. Sand cultures of mangels, supplied sodium and chlorin separately and in combination, have developed most favorably in the latter case. Soil cultures of sugar beets in the greenhouse, where sodium chlorid was supplied, have exceeded in yield the control unfertilized cultures. The percentage of sucrose in the dry matter has also increased where the chlorin was added. Plat experiments in the field with sugar beets at Madison, Wis., are said to show increased yields due to the application of sodium chlorid, the increase amounting to as much as 500 lbs. per acre.

The experiments are to be continued, a variety of plants being tested, in the belief that in some plants at least chlorin may be found to function in specific nutrient effects.

Localization of manganese ions in roots as related to the formation of proteid substance, G. D'IPPOLITO and A. PUGLIESE (*Staz. Sper. Agr. Ital.*, 47 (1914), No. 3, pp. 231-240, pls. 3).—The authors present some results of experiments with wheat grown in aqueous or nutritive solutions containing manganese compounds. The claims of Acqua (*E. S. R.*, 31, p. 325) regarding coloration as indicating and locating the utilization of such compounds are also reviewed in this connection.

The localization of manganese in plants, C. ACQUA (*Ann. Bot. [Rome]*, 12 (1914), No. 3, pp. 361-368).—This is a reply to the above note.

Toxicity and malnutrition, R. H. TRUE (*Science, n. ser.*, 42 (1915), No. 1075, pp. 195, 196).—The author discusses the terms "toxicity" and "poison" in relation to their physiological significance, and attempts to arrive at a more definite understanding regarding their use. The most satisfactory solution of the problem seems to lie in the supposed relation existing between ions and the protein of the living organism.

The action of potassium cyanid when introduced into tissues of a plant, W. MOORE and A. G. RUGGLES (*Science, n. ser.*, 42 (1915), No. 1070, pp. 33-36).—In a previous publication (*E. S. R.*, 32, p. 152) an account is given of experiments by Sanford on the destruction of *Icerya purchasi* by the use of potassium cyanid placed in the tissues of the tree. The authors have carried on experiments with potassium cyanid placed in the stems of geranium plants and also in apple trees to determine the path of translocation of the introduced substance.

As a result of their investigations they conclude that the treatment would have little or no value for the larger number of wood-boring insects, as the hydrocyanic acid does not travel in the cambium of the trees, but only through the old tracheæ. For the herbaceous and semiwoody plants the presence of the chemical, it is believed, would endanger the life of the plant.

The amount of creatinin in plants, M. X. SULLIVAN (*Abs. in Science, n. ser.*, 42 (1915), No. 1071, p. 69).—Investigations of the author have shown the occurrence of creatinin in plants, the quantity having been determined in recent experiments. Only from 1 to 6 parts per million were found in ungerminated seed of wheat and soy bean. The amount increased during germination, and in wheat seedlings 10 to 12 days old, from 40 to 65 parts per million of creatinin were found.

The formation of creatinin by bacteria, M. X. SULLIVAN (*Abs. in Science, n. ser.*, 42 (1915), No. 1071, p. 69).—In experiments by the author it was found

that a trace of soil added to a protein-free synthetic culture medium, with ammonium sulphate as the source of nitrogen, led to the development of a strong growth of bacteria. Analysis made six months after inoculation of the soil showed the presence of creatinin, as indicated by color reactions and by the formation of creatinin zinc chlorid.

The assimilation of carbon and nitrogen compounds by mold fungi, A. Kossowicz (*Biochem. Ztschr.*, 67 (1914), No. 4-5, pp. 391-399).—More recent study (E. S. R., 32, p. 728) of the nutritional relations between ten widely divergent and common mold fungi named, and several carbon and nitrogen compounds is claimed to have shown that in pure cultures these fungi were each able to utilize as the sole nitrogen source, uric acid, hippuric acid, glycocholl, guanin or its compounds, calcium cyanamid, nitrites, or nitrates, and urea, and as a carbon source any of the first four above-named substances.

The relation of yeasts and molds to nitrates, A. Kossowicz (*Biochem. Ztschr.*, 67 (1914), No. 4-5, pp. 400-419).—Results are detailed of several series of experiments in which some or all of the ten fungi employed in the studies above noted were found to reduce nitrate in the nutritive medium to nitrite. Results with yeasts were either less definite or else negative.

The nitrate ferment and the formation of physiological species, M. W. Beljerinck (*Folia Microbiol. [Delft]*, 3 (1914), No. 2, pp. 91-113, pl. 1).—Discussing results of further investigations (E. S. R., 32, p. 523), the author contrasts these ferments with some related kinds and discusses the difficulty or impossibility here illustrated of distinguishing sharply between mutations and hereditarily stable modifications. The two kinds of nitrate ferment are claimed to be clearly distinguishable.

Influence of hybridization and cross-pollination on the water requirement of plants, L. J. Briggs and H. L. Shantz (*U. S. Dept. Agr., Jour. Agr. Research*, 4 (1915), No. 5, pp. 391-402, pl. 1, fig. 1).—It having been suggested by Collins (E. S. R., 24, p. 236) that hybridization might result in increased drought resistance, the authors report on a study of the water requirements of 8 first generation maize hybrids and 1 wheat hybrid (a cross between *Triticum durum* and *T. aestivum*). The measurements were made at Akron, Colo., from 1912 to 1914, the methods previously described (E. S. R., 29, p. 825) being employed.

From the data presented, it appears that "the hybrids ranged in water requirement from 10 per cent below to 10 per cent above the parental mean. On the basis of the results so far obtained, the chances are even that a maize hybrid will not depart in its water requirement more than ± 6 per cent from the parental mean. Cross-pollination between individual plants of maize leads to results similar to hybridization of different strains, so far as water requirement and yield are concerned. A wheat hybrid which had been grown for several generations gave a water requirement 14 per cent above the mean water requirement of the parental strains."

The relation between light intensity and the formation of essential oil, V. Lubimenko and M. Novikov (*Trudy Būuro Prikl. Bot. (Bul. Appl. Bot.)*, 7 (1914), No. 11, pp. 697-727).—In studies carried out with *Ocimum basilicum* under illumination of different intensities, the author claims to have shown that the development of plant organs and production of essential oil bear a relation to the intensity of illumination to which the plant is subjected.

A gradual decrease of intensity leads to a preponderance of development of the vegetative portions over that of both flowers and fruits. The stems attain their maximum weight under stronger illumination than that required for such attainment in case of the leaves. Production of dry substance in this plant as a whole attains its maximum in somewhat attenuated daylight, diminishing rapidly with departure in either direction from this point. Light seems to act

directly upon the formation of essential oil in the leaves, flowers, and fruits, such production being retarded by an increase of illumination, and the optimum being reached in subdued daylight. The optimum light intensity for oil production is, moreover, below that for production of dry matter. Some bearings of these facts are discussed.

Artificial photosynthesis by means of chlorophyll, W. J. V. OSTERHOUT (*Abs. in Science, n. ser.*, 42 (1915), No. 1071, p. 68).—The author states that if Schryver's test for formaldehyde is specific, experiments show that formaldehyde produced from chlorophyll acting in the presence of carbonic acid in sunlight is due to the decomposition of the chlorophyll and not to photosynthesis, as has been supposed to be proved. Other pigments, as methyl green, iodine green, and a variety of other stains, exposed to sunlight under the same conditions as chlorophyll, also give the test for formaldehyde. From this it is considered that artificial photosynthesis by means of sunlight has not yet been accomplished.

The effects of electrolytes on oat seeds, F. PLATE (*Ann. Bot. [Rome]*, 12 (1914), No. 3, pp. 261-343).—After a review of reports by others on related studies, the author gives in considerable detail the results of his own more recent work (*E. S. R.*, 30, p. 228; 33, p. 521). The numerous organic and inorganic compounds employed are arranged in seven general groups according to their observed relations as noted in regard to their absorption and their effects on the germination and development of the seeds.

A new device for sterile preservation of seeds, M. PLAUT (*Ber. Deut. Bot. Gesell.*, 32 (1914), No. 7, pp. 466-471, figs. 3).—A description is given of a combination cap of wire gauze and cotton wool for closing vessels intended to contain seeds for preservation, experimentation, etc. This is expected to give at low cost complete protection with safety, convenience, and ease of manipulation.

The heredity of fasciation in *Bunias orientalis*, R. PIROTTA and M. PUGLISI (*Ann. Bot. [Rome]*, 12 (1914), No. 3, pp. 345-360, pls. 6).—As a result of the preliminary study here described, the authors consider the tendency to fasciation in *B. orientalis* (*Lathra orientalis*) to be hereditary.

Flora of New Mexico, E. O. WOOTON and P. C. STANDLEY (*U. S. Nat. Mus., Contrib. Nat. Herbarium*, 19 (1915), pp. 794).—This flora of New Mexico is based largely upon the authors' collections, supplemented by all the available material to be found in the principal herbariums of the world. Both the authors were for a time connected with the New Mexico Experiment Station, from which point their collecting work was largely done.

About 3,000 species of flowering plants and vascular cryptogams are included in the publication. Keys are given to the genera and species so that this flora may be used as a field manual in the region covered.

Tropical North American species of *Panicum*, A. S. HITCHCOCK and AGNES CHASE (*U. S. Nat. Mus., Contrib. Nat. Herbarium*, 17 (1915), pt. 6, pp. XII+459-539, figs. 139).—In a preceding paper (*E. S. R.*, 24, p. 432) the authors presented a revision of the North American species of *Panicum*. The present contribution is the result of further studies of the tropical species which were not fully treated in the previous publication. Keys are given for all the tropical species, although descriptions are not always included. The authors list 116 species and 3 subspecies, 9 of which are described as new.

FIELD CROPS.

On a criterion of substratum homogeneity (or heterogeneity) in field experiments, J. A. HARRIS (*Amer. Nat.*, 49 (1915), No. 583, pp. 430-454, figs. 3).—In this article the author points out the need of some generally applicable meas-

ure of the degree of homogeneity of the soil of an experimental field, and proposes as a scientific criterion the coefficient of correlation between neighboring plats of the field. An exceedingly simple formula for the calculation of such coefficients has been deduced.

“Let S indicate a summation for all the ultimate or combination plats of the field under consideration, as may be indicated by the capital Cp or lower case p . Then in our present notation, which is as much simplified as possible for the special purposes of this discussion,

$$r_{p_1 p_2} = \frac{\{[S(Cp^2) - S(p^2)]/m[n(n-1)]\} - p^{-2}}{\sigma p^2}$$

where P is the average yield of the ultimate plats and σp their variability, and n is constant throughout the m combination plats.” The method of application of this coefficient is illustrated by the use of published records of several investigators, involving experiments with mangolds, wheat, and timothy hay.

“The remarkable thing about the results of these tests is that in every case the coefficient of correlation has the positive sign and that in some instances it is of even more than a medium value. In short, in every one of these experimental series the irregularities of the substratum have been sufficient to influence, and often profoundly, the experimental results.”

It is noted that nothing could “emphasize more emphatically the need of a scientific criterion for substratum homogeneity than the facts that correlations between the yields of adjacent plats ranging from $r=0.115$ to $r=0.609$ can be deduced from the data of fields which have passed the trained eyes of agricultural experimenters as satisfactorily uniform.”

[Field crops] work of the Truckee-Carson reclamation project experiment farm in 1914, F. B. HEADLEY (*U. S. Dept. Agr., Bur. Plant Indus., Work Truckee-Carson Expt. Farm, 1914, pp. 1-9*).—This reports the progress of work at the experiment farm near Fallon, Nev. (*E. S. R.*, 31, p. 828), and near-by farms. Weather records are given and data as to agricultural conditions, which include acreage, yields, and farm values of the main money-producing crops in 1914 and a comparison of the data with those of 1912 and 1913.

Yields in variety tests with 11 varieties of alfalfa ranged from 72 to 134 lbs. per 100-ft. row, with four varieties of fodder corn, from 13.53 to 19.85 tons per acre of green weight; with six varieties of wheat, from 16.3 to 31.8 bu. per acre; with six varieties of oats, from 16.6 to 24.5 bu. per acre; with 24 varieties of corn, from 554 to 1,300 lbs. per acre; and with 22 varieties of potatoes, from 4 to 61 lbs. of marketable tubers per 100-ft. row.

[Field crops work at the Canadian stations and farms in 1913], J. H. GRISDALE ET AL. (*Canada Expt. Farms Rpts. 1914, pp. 3, 4, 15-19, 22-24, 28, 29, 38-40, 41, 42, 45, 48, 52, 53, 55, 56, 58, 59, 60, 63, 64, 67, 68, 72, 73, 77, 78, 80, 81, 83, 104-109, 119-123, 141-180, 183-291, 510, 511, 557-559, 560, 563-566, 575, 576, 580-582, 587, 588, 608-613, 643-646, 670, 683, 684, 686, 695, 698, 718, 719, 725, 726, 743, 752-828, 881-940, 941-950, 995-1022, pls. 18*).—This reports the continuation of work previously noted (*E. S. R.*, 32, p. 431) and is a detailed account of the work already mentioned (*E. S. R.*, 30, p. 829; 32, pp. 530, 532), with meteorological data and additional data on variety and manurial tests with potatoes, tobacco, and sugar beets.

Experiments with spring grain in 1914, P. R. FEDOROV (*Bezenchuk. Sel'sk. Khoz. Opytn. Stantsiia, No. 58 (1914), pp. 13*).—In a 4-field rotation system the crops preceding wheat were peas, corn, sunflowers, millet, potatoes, carrots, and wheat. The greatest yields were after potatoes and carrots, the smallest after wheat and sunflowers.

In a depth-of-plowing test for seeding wheat, 4 verchoks (7 in.) gave better results than 2½ or 5½ verchok depths. August proved a better time to plow than July or September. Heavy seeding, 9 poods per dessyatina (120.2 lbs. per acre), gave better results than light seeding.

In fertilizer tests barnyard manure gave the best results. Phosphates seemed to reduce the yield. Native varieties gave the largest yields and Egyptian the smallest.

There were no parasites on oats during the year. A large number of empty grains resulted from the drought. The depth of plowing best suited was found to be 4 verchoks for the crop preceding the oats and 5 verchoks for the oats.

In fertilizer tests barnyard manure, manure combined with Thomas slag, and Thomas slag alone were used. The manure, either alone or in combination, apparently did not increase the yield of oats, though somewhat improving the quality of the grain, while Thomas slag alone increased the yield by 11.4 per cent.

Of oats sown broadcast, 5 to 7 poods per dessyatina, in rows with from 4 to 7 poods per dessyatina, in wide single and double rows with from 3 to 5 poods per dessyatina, and at distances varying from 6 to 8 verchoks, the best method proved to be sowing in wide single rows at a distance of 8 verchoks.

Wild white clover, A. N. M'ALPINE (*Trans. Highland and Agr. Soc. Scot.*, 5. ser., 27 (1915), pp. 238-256).—This article treats of wild sweet clover (*Trifolium repens sylvestre*), discussing its distinguishing characters, agricultural value, ecology, characteristics of the commercial seed, and its growth and development.

Corn, C. P. BULL (*Minnesota Sta. Bul.* 149 (1915), pp. 5-23, figs. 7).—This bulletin gives a detailed report of work previously noted (*E. S. R.*, 28, p. 233) and additional results on corn cultural experiments.

As the result of different methods of cultivation for three years, it is concluded that "to a certain degree the lack of cultivation is attended with an increased percentage of barren stalks. Though the 'twice-cultivated' plat is an exception, the increase in the number of cultivations seems to have a tendency to lower the percentage of stand. The difference in the plats is, however, not sufficient to warrant a definite conclusion. The height of the stalks and of the ears on the stalk does not appear to be influenced by the cultivations, except that with no cultivation they are considerably lower. The yield per acre of corn is the important item in the results of this experiment. The averages for the plats show conclusively that the number of cultivations materially affects the yield per acre. The yield of stover also increases regularly with the number of cultivations. It is plain that two cultivations are not sufficient to subdue the weeds and give the proper start to the vegetative growth of the plants. It is quite likely that the relative time of cultivation has something to do with the value, but that was not considered in this experiment.

"Another important fact shown is that it is not necessary to practice deep tillage when once the soil has been properly prepared before planting. The average yield of the hoed plat exceeded the highest yield obtained from any other. It exceeded that of the plat cultivated six times by 1.46 bu. per acre.

"The data show that the large profit from cultivation comes from the fourth cultivation and that there is but slight gain from three cultivations over two cultivations, the profit amounting to but 53.2 cts. more than the cost of the operation."

In a study covering five seasons of the relation of the number of stalks per hill to yield, where the hills were spaced 44 by 44 in., the results show that not only the number but also the percentage of barren stalks increased as the number of stalks per hill increased, but that the difference in percentage stand in check rows was not sufficient to be regarded as significant. The percentage

stand in the drill row was nearly perfect, thus indicating that the chances of securing a perfect stand are about 5 per cent better by planting in drills. A large number of stalks per hill (6, 7, or 8) impaired the growth, as shown by the short plants and low ears in these hills. The percentage of marketable ears decreased as the number of stalks per hill increased. The maximum yield per acre was reached with four stalks per hill, with three stalks per hill yielding only a fraction of a bushel less, followed by five stalks per hill. Six stalks per hill yielded higher than two stalks.

The percentage of marketable ears harvested from corn planted 2, 3, 4, 5, and 6 stalks per hill were 81.4, 66.37, 54.45, 38.75, and 30.37, respectively, while that of corn planted 18 in. apart in drills 44 in. apart was 82.07.

Single-stalk cotton culture at San Antonio, R. M. MEADE (*U. S. Dept. Agr. Bul. 279 (1915), pp. 20, pls. 6, figs. 3*).—This bulletin gives results of trials in 1914 of the single-stalk cotton culture method (E. S. R., 32, p. 434) in comparison with the usual wide-spacing method. Data show the average number of vegetative branches on plants in wide-spaced and in single-stalk rows, the daily flower census of single-stalk and wide-spaced plants, the number of bolls matured on wide-spaced and single-stalk rows, the ratio of 3, 4, and 5 locked bolls, and the yields by the two methods of culture. "The single-stalk and wide-spaced systems of culture were compared in alternate single rows and alternate 4-row blocks in rows 4 ft. apart and again in alternating rows 3, 4, 5, and 6 ft. apart. In one instance plants were thinned early, late, and very late to 6, 9, 12, 18, and 24 in. apart. The stand was satisfactory in all cases. . . .

"More flowers were produced daily on the single-stalk rows than on the adjoining wide-spaced rows. At the end of 40 days single-stalk rows alternating with wide-spaced rows had produced 84 per cent more flowers than the latter. In alternating blocks single-stalk rows had produced 78 per cent more flowers than wide-spaced rows in the adjoining block.

"Single-stalk rows produced an average of 5.5 bolls per plant and wide-spaced rows 8.6 bolls per plant. The difference in the number of bolls per plant was much more than offset by the greater number of plants in the single-stalk rows, so that the single-stalk rows set from 50 to 150 per cent more bolls in the same row space. A larger percentage of 4-locked bolls was produced in single-stalk rows and in rows close together than in wide-spaced rows where the plants were set either close together or far apart. The bolls in the single-stalk rows were slightly smaller than those in the wide-spaced rows. Nineteen 4-locked bolls from single-stalk rows were required to equal the weight of 18 4-locked bolls from wide-spaced plants. The ratio of weight for 5-locked bolls is 11:10 for single-stalk and wide-spaced rows, respectively.

"The plants in single-stalk rows were taller than those in wide-spaced rows. The single-stalk rows were spreading at the top, while the wide-spaced rows were broader near the ground. In all cases single-stalk rows yielded more than the adjoining wide-spaced rows, regardless of the distance between the rows. An examination of the fiber in the field showed that there was no perceptible difference in the quality or quantity of lint produced in single-stalk and in wide-spaced rows.

"Plants thinned to a few inches apart in the row had fewer vegetative branches than plants spaced farther apart, the thinning having been done at the same time in each case. Late-thinned plants had fewer vegetative branches than plants thinned earlier to the same distance. Early thinning and late thinning gave higher yields than very late thinning."

Improvement of cotton in the Bombay Presidency (except Sind), K. D. KULKARNI and G. L. KORTUR (*Dept. Agr. Bombay Bul. 70 (1915), pp. 43*).—This bulletin gives lists and descriptions of some 300 varieties of native and 300

varieties of introduced cotton and their hybrids grown in various parts of the Bombay Presidency since 1905, with brief notes regarding the performances of some of the selections and hybrids.

Flax culture, R. KUHNERT (*Der Flachsbau. Berlin: Deut. Landw. Gesell., 1915, 3. ed., pp. XV+34*).—A revised and enlarged third edition of a book previously noted (E. S. R., 14, p. 960).

Experiments on the development of oats under the influence of irrigation and root pruning, B. SCHULZE (*Landw. Vers. Stat., 86 (1915), No. 1-2, pp. 63-74*).—Oats grown in a series of six concrete pots and receiving during the growing period, aside from the seasonal precipitation, no water and 1.3, 1.69, 1.91, 2.11, and 2.34 times as much water as the seasonal precipitation, produced, respectively, 132.5, 160.7, 176.1, 191, 178.7, and 187.4 gm. of grain per pot. For each 100 liters of water the amount of dry matter produced per pot was 621, 580, 504, 472, 421, and 377 gm. The ratios of grain to straw were for each pot 1:1.9, 1:1.91, 1:1.99, 1:1.91, 1:2.08, and 1:1.91; and the ratios of tops to roots, 100:14.8, 100:12.4, 100:11.9, 100:9.8, 100:11.7, and 100:12.9, respectively.

For the study of root pruning, oats were grown in concrete pots that permitted of the introduction of an iron plate so as to cut horizontally the contents of the pot at a required depth. Oats planted on March 20 were pruned on May 2 at a depth of 30 cm., and on May 16 and 30, June 15, and July 1 at 40 cm., respectively. The harvest of grain from each of these pots in August was 148, 117.5, 85.9, 67.3, and 158.4 gm., respectively, and 161.9 gm. from the pot not pruned. The ratios by weights of the tops to the roots were 100:10.4, 100:10.1, 100:11.1, 100:10.7, 100:6.8, and 100:9.9.

It is noted that a shortening of the roots during the period of shooting and blossoming of the plant was the most injurious, and that this injury seemed to lie in a reduction of the food supply rather than a cutting off of the water supply.

Oats for North Carolina, C. B. WILLIAMS (*North Carolina Sta. Circ. 30 (1915), pp. 8, figs. 2*).—This circular gives cultural suggestions for the oat crop when grown alone and in combination with crimson clover, vetch, and rape. Rotations, including oats, for the various sections are suggested.

Experiments with potatoes, P. R. FEDOROV (*Bezenchuk. Selsk. Khoz. Opytn. Stantsiia, No. 59 (1914), pp. 9*).—This report shows that deep plowing, 5½ verchoks (9.62 in.), gave better results than shallow depths, and large seed tubers planted whole better results than small, medium, or cut pieces. In a spacing test 12 verchoks (21 in.) square gave the best results. In manurial tests Thomas slag alone gave higher yields than barnyard manure, either alone or with Thomas slag. The potatoes from the unfertilized soil gave the highest percentage of starch, 17.6 per cent, but the lowest yield.

Soy bean growing in North Carolina, C. B. WILLIAMS (*North Carolina Sta. Circ. 31 (1915), pp. 8, figs. 3*).—This circular gives instructions for the production of the soy bean crop in North Carolina. Brief notes discuss the crop as grown for hay, seed, soil improvement, soiling, and pasture.

Experiments with fertilizers and manure on tobacco grown continuously and in rotation with wheat and clover, C. E. THORNE (*Ohio Sta. Bul. 285 (1915), pp. 210-221, figs. 2*).—This reports the continuation of work begun in 1903 and previously noted (E. S. R., 22, p. 23). Data show the yield and increase of tobacco grown continuously and of that grown in rotation with wheat and clover, with various fertilizer treatments of the soil, covering 6, 5, and 4 year periods. In the rotations the fertilizer applications were made to the tobacco crop only.

Yields from soils that received a complete fertilizer consisting of 320 lbs. of acid phosphate, 60 lbs. of muriate of potash, and 320 lbs. of nitrate of soda per acre were much more profitable than those from any form of partial fertilizer. When the amount of potash in the complete fertilizer was increased the yield was not increased and the quality was reduced. The substitution of either nitrate or sulphate of potash for the muriate showed a reduction in yield. When the phosphorus in the rotation experiment was increased there was a marked gain in the yield, a greater total yield, and a greater net profit than with any other in the series. The omission of phosphorus reduced the increase to the lowest point in the series. The next highest total yield and net profit was by the increased amount of nitrogen.

Comparing nitrate of soda with sulphate of ammonia as carriers of nitrogen, and again with lime, there was an apparent loss for the sulphate of ammonia in the absence of lime and a gain when lime was added. Nitrogen and phosphorus were applied as tankage at a disadvantage to both yield and net profit. Barnyard manure used at the rate of 10 tons per acre produced yields to an average value of \$5 per ton of manure. Reinforcing the manure with phosphorus (40 lbs. of floats to the ton of manure) materially increased its effectiveness. The data show that lime was apparently not needed on this soil, as the only plat which showed any decided benefit from lime was the one receiving its nitrogen in sulphate of ammonia.

A general comparison of the continuous and rotative cropping of tobacco shows that the annual value of all the crops has been smaller in the rotative than in the continuous cropping, because of the much higher acre-value of tobacco than of wheat or clover. "On the unfertilized land the average annual total yields for the two 6-year periods of the test have been 399 and 319 lbs. for the continuously grown tobacco and 576 and 536 lbs. for that grown in rotation, thus showing that a clover sod has produced 177 and 217 lbs. of tobacco per acre during the two periods in excess of that grown on tobacco stubble."

Tobacco: Influence of fertilizers on composition and quality, J. W. AMES and G. E. BOLTZ (*Ohio Sta. Bul.* 285 (1915), pp. 173-209, figs. 6).—This gives results of experiments conducted at Germantown, Ohio, on light clay loam in which organic and mineral fertilizers were used in varying combinations and quantities to determine their influence on the composition and quality of the tobacco grown. Data show the amounts of fertilizers used and the resulting yields in wrapper, filler, and trash for 1912, the total average annual yields for a period of six years, the percentage content of carbon-free ash, Ca, Mg, Mn, Na, K, P, total N, nitrate N, nicotin, total S, S as sulphates, and Cl of the resulting crop, and the results of smoking tests in regard to fire-holding capacity, flavor, and aroma.

The methods which were used in collecting and preparing the samples and in making the chemical determinations are described.

"The results show that the composition has been modified to a greater or less extent by different fertilizer treatments. The several lots of tobacco have a high ash content. When sodium nitrate is applied there has been, in most instances, a decrease in total ash, phosphorus, sulphur, and chlorin. Of the essential elements present, calcium is found in largest amount, followed by nitrogen, potassium, magnesium sulphur, and phosphorus. The addition of lime to the soil has decreased the calcium and increased the magnesium in the tobacco. A complementary relation is found to exist between the calcium and magnesium, when the one is high and the other is low. Tobacco from limed plats, as a rule, contains less phosphorus, potassium, and sulphur than that from unlimed plats. Relatively small amounts of phosphorus are removed by the crop, as compared with other constituents which are regarded as less essential

for plant growth. The highest percentage of nitrogen is found in tobacco from unfertilized soil. Where organic carriers of nitrogen were applied the percentage of nitrogen in tobacco leaves is higher than where inorganic materials supplied the nitrogen. Tobacco from plats to which organic carriers of nitrogen, shed manure, and tankage were applied have a higher nitrate nitrogen and nicotine content.

"While tobaccos from plats treated with potassium salts contain more potassium than where none was applied, the amount present is influenced by the carrier of this element. Tobacco from sulphate or nitrate of potash plats contains larger amounts of potassium than that from muriate of potash treated plats, fertilized with like carriers and quantities of phosphorus and nitrogen. Sodium nitrate has tended to increase the potassium content. The smallest amount of potassium is found in case of untreated land, and the largest amount in tobacco from the manure-treated plat, which is in accord with the large amount of potassium furnished by 20 tons of manure. The carrier of potassium used has decidedly influenced the amounts of chlorin and sulphur in the tobacco leaf, but certain conditions of fertilization have so modified the amounts of potassium and chlorin or sulphate present that no direct relation exists between them. The chlorin content is in close agreement with the excess of chlorin supplied to the soil by muriate of potash, the largest amount being present in tobacco from soil receiving the heaviest application of muriate.

"Tobacco from the manure-treated plat contains more chlorin than any of the other tobaccos not fertilized with muriate of potash. This is in agreement with the amount of chlorin furnished by 20 tons of manure. The amount of chlorin present in this case, 1.32 per cent, has not impaired the quality of the tobacco. Acid phosphate, when used in combination with muriate of potash, tends to increase the chlorin content, while nitrate of soda decreases it. While the sulphur content of tobacco is normally greater than the chlorin, when no excessive amount of chlorin has been furnished, the addition of sulphates in the fertilizing material has modified the sulphur content in a much less degree than has been found with regard to the chlorin following treatment with muriate of potash.

"Smoking tests of cigars from the several lots of tobacco show that the quality of tobacco is impaired where muriate of potash is used in the fertilizer. Tobaccos with a low chlorin content have a good fire-holding capacity in contrast with the tobacco containing excessive amounts of chlorin, due to the fertilizer treatment. All the tobaccos with a high chlorin content had a black, charred ash, which in some instances did not cohere with the ash of the binder and wrapper, with the result that the ash of the binder and wrapper shattered easily. The average length of time the cigars made from tobacco from the muriate-treated plats held fire was approximately half that for tobacco from plats treated with sulphate or nitrate of potash. Muriate of potash was included with varied combinations of phosphorus and nitrogen, so that differences observed in burning quality are due in part to other influences. Although muriate of potash when used with acid phosphate and nitrate of soda increased the yield above that obtained by the use of other forms of potash, any improvement in this respect has been more than offset by poor quality of the tobacco.

"Potassium when used in other combinations than the chlorid improved the quality of the tobacco. The quantity of sulphur as sulphates present in the tobacco exerted very little, if any, influence on the burning quality. Acid phosphate alone improves the quality of the tobacco; when applied in combination with muriate of potash, any favorable effect produced appears to be counteracted. Variations in flavor, aroma, and fire-holding capacity are not due

entirely to the presence or absence of any one compound, but are more or less dependent upon the total constituents of the tobacco."

Tobacco growing in Minnesota, C. P. BULL (*Minnesota Sta. Bul.* 150 (1915), pp. 7-47, figs. 26).—This gives a survey of the progress of the tobacco industry for the period from 1909 to 1914, inclusive, together with cultural, harvesting, and curing directions for Minnesota growers. Cost accounts show the total cost to range from \$25 to \$45 per acre and the yields from 755 to 2,100 lbs. per acre.

Hairy vetch, V. M. SHOESMITH (*Michigan Sta. Circ.* 27 (1915), pp. 3-8, figs. 2).—This deals with cultural methods and the uses of vetch as a green manure, forage, or seed crop, and in rotation with wheat.

Spacing and depth of planting for spring wheat, A. D. BOCHKOVA (*Zhur. Opytn. Agron. (Russ. Jour. Expt. Landw.)*, 14 (1913), No. 2, pp. 43-63).—In experiments in spacing wheat so as to allow 25, 50, 75, 100, 125, 150, 187, 225, 300, and 400 sq. cm. per plant, it was found that the total yield per plant increased with the increase of area per plant. The closer the spacing the better was the quality of the grain, the greater the weight of 1,000 kernels, and the higher the yield per unit of area.

In tests of depth of planting a difference between 6 and 7 days was observed in the appearance of the seedling when planted at depths of 2, 4, 5, 8, and 10 cm. The germinative ability was noted to decrease with the increase in depth of planting. Tillering and shooting occurred at the same time for all depths, but the degree of tillering decreased with the depth of the seed. After the shooting the higher temperature seemed to hasten the development of the plants from the deep-planted seeds so that the spike matured two or three days earlier than those from the shallow-planted seeds. The length of spike and number of kernels per spike increased with the depth of planting, while the weight of the kernels diminished. The total yield and yield of grain increased with the depth of seed, while the proportion of straw decreased.

Some quantitative data from laboratory investigations of seeds of rye and oats, N. LEONTEVSKII (*Abs. in Zhur. Opytn. Agron. (Russ. Jour. Expt. Landw.)*, 15 (1914), No. 2, pp. 184, 185).—This gives results of seed examinations and chemical analyses of rye and oats grown in various parts of the Government of Vologda.

Weediness of fields and influence thereon of various methods of husbandry, P. I. LESHCHENKO (*Trudy Poltav. Selsk. Khoz. Opytn. Stantsii*, No. 25 (1914), pp. VIII+79, figs. 8).—At the Poltava Experiment Station the following observations were made:

For each cultivated plant there were one, two, or more weeds, and for each unit of the green weight of grain from one to two units of weeds. Both in winter and spring cereals annual weeds were in greater number than the perennials. The winter cereals had a larger quantity of weeds than the spring, and also, according to the weight of grain, more annual and biennial weeds, while in the spring cereals there were more perennial weeds.

The predominant annuals and biennials in winter cereals were *Viola tricolor*, *Sclerantus annuus*, *Capsella bursa pastoris*, and *Tlaspi*, which are typical for a 3-course crop rotation with later fertilization. All these developed completely and produced seed. For spring cereals with a 3-course crop rotation the typical weeds were *Setaria glauca*, *Stachys*, *Polygonum aviculare*, several species of *Vicia*, and *P. convolvulus*.

Experiments covering a period of 19 years showed that in a 3-course crop rotation of late fertilization caused *Avena fatua* and *Centaurea cyanus* to disappear entirely, while *Matricaria* and *Triticum repens* occurred very seldom. Where early fertilization had been practiced, annual and biennial weeds char-

acteristic for the same fields with late fertilization were entirely eliminated. Winter cereal fields produced at harvest time young shoots of annual weeds typical for spring cereals.

Early fertilization in the rotation, however, increased the weediness of spring cereals, these being covered with annuals typical for this field with seeds which were large, covered with a hard envelope, and ripened either at the time of harvesting the grain or after it. Early fertilization did not crowd out the seeds of such weeds nor entirely eliminate the number of perennial weeds, although that of thick-stemmed weeds was decreased.

HORTICULTURE.

Report from the division of horticulture for the year ended March 31, 1914, W. T. MACOUN ET AL. (*Canada Expt. Farms Rpts. 1914, pp. 492-510, 512-552, 553-557, 559, 561, 562, 566-574, 577-580, 582-586, 588-602, 603-608, 614-642, 647-669, 670-682, 685, 686-692, 696, 697, 698-718, 719-725, 727-743, 744-748, pls. 9*).—A detailed report on results secured in 1913 in the breeding and cultural experiments with fruits, vegetables, forest and ornamental trees, and herbaceous plants conducted at the Central Farm, Ottawa, and at the various branch experimental farms and stations in Canada. A summary of these results has appeared previously in bulletin form (E. S. R., 32, p. 539).

[**Variety tests with vegetables**], F. B. HEADLEY (*U. S. Dept. Agr., Bur. Plant Indus., Work Truckee-Carson Expt. Farm, 1914, pp. 9, 10*).—Ripening dates and yields are given for varieties of tomatoes tested on the Truckee-Carson farm in 1914, together with yields of onion varieties grown on a farm at Fallon, Nev., in 1914. The five highest-yielding tomato varieties in the test were the Perfection, Ponderosa, Globe, Acme, and Beauty. Of the onions, Prizetaker, Ohio Yellow Globe, and Red Wethersfield appeared to be the most desirable varieties for commercial purposes.

Insecticides and fungicides, F. T. SHUTT (*Canada Expt. Farms Rpts. 1914, pp. 123-126*).—Analyses are reported of arsenate of lead, formaldehyde, pine spray insecticide, worm killer, Velvas lawn sandweed killer and fertilizer, and tobacco decoction.

Orchard spraying, D. E. LEWIS (*Kansas Sta. Bul. 203 (1915), pp. 5-44, figs. 15*).—In this bulletin consideration is given to spray materials and machinery, mixing and testing the common orchard spray solutions, the method of applying each, and the acreage which each type of spray machine may be expected to protect. A spraying outline is also given showing the dates and kind of material to use in protecting the fruit crop from the common orchard pests.

Some effects of pruning, root pruning, ringing, and stripping on the formation of fruit buds on dwarf apple trees, A. W. DRINKARD, JR. (*Virginia Sta. Tech. Bul. 5 (1915), pp. 96-120, figs. 9; Rpts. 1913-14, pp. 96-120, figs. 9*).—An account is given of experiments begun in the spring of 1913 for the purpose of determining the effects of root pruning, ringing, and stripping at different seasons on the formation of fruit buds on apple trees. The observations and results here reported cover a period of two years and include only full dwarf apple trees of the English variety King of Pippins. The work has now been extended to include half dwarf and standard apple trees growing under a variety of conditions.

The results thus far secured with dwarf trees show that spring pruning of the branches of the trees at the time of growth resumption had a tendency to discourage the formation of fruit buds, but appeared to stimulate the wood growth. Summer pruning of the branches during the latter part of June, when fruit buds normally begin to show differentiation, checked wood growth for the

year and greatly stimulated the formation of fruit buds. Fall pruning of the branches in November did not materially influence the crop of fruit buds, but caused vigorous wood growth the following year.

Severe root pruning in the spring, whether at the time of growth resumption, when the leaves were well developed, or at the beginning of fruit bud differentiation, when accompanied by or preceded by spring pruning of the branches produced some stimulation in fruit bud formation. Root pruning retarded growth in the current and succeeding year, the leaf area of the trees being reduced and the trees showing injury from the treatment. The earlier the root pruning was done the greater was the injury. Root pruning without branch pruning at the resumption of growth did not give as much stimulation to fruit bud formation as the same treatment applied at later dates.

Ringling at different seasons when accompanied by or preceded by spring pruning of the branches produced no noticeable stimulation of fruit buds. Ringling alone early in the season did not stimulate fruit bud formation. Ringling alone at the time the leaves were fully developed gave the best results, although some stimulation to fruit bud development was observed when the ringling was done at the time of differentiation of the fruit buds.

The effects of stripping the trees were offset by spring branch pruning. Stripping at the three seasons already mentioned without branch pruning stimulated fruit bud formation uniformly.

Thus far our knowledge of special practices, such as root pruning, ringling, and stripping, is deemed too meager to formulate rules for their use in orcharding.

Cranberry growing, H. J. FRANKLIN (*Mass. Bd. Agr. Circ. 41 (1915), pp. 31, pl. 1*).—In this paper the author gives a brief discussion of the important essentials for the growing of cranberries, their handling for market, and their preparation for the table, together with an itemized estimate of the present cost of preparing a bog.

Utilization of peat land for cranberry culture, C. L. SHEAR (*Jour. Canad. Peat Soc., 4 (1915), No. 1, pp. 15-18*).—In this paper the author gives the essentials for successful and profitable cranberry culture, with special reference to the utilization of peat land.

Contribution to the history of the vine and its culture in the Lorraine region, J. RISTON (*Contribution a l'Histoire de la Vigne et de sa Culture dans la Région Lorraine. Nancy: Librairie Sidot Frères, 1914, vols. 1, pp. 596; 2, pls. 33*).—In the introductory chapter of this two-volume work the author summarizes the characteristics and delimits the Lorraine region. Part one comprises a historical account of grapes and the grape industry in this region. Part two consists of a study of the cultivated grapes in Lorraine. Part three reviews the knowledge relative to the climate of the region. Part four treats of the culture of the vine, and part five comprises a study of the decadence of the Lorraine grape industry. Volume two comprises photographic illustrations of the foliage of the principal grapes, together with maps of the regions studied.

The results of experiments with citrus stocks.—The first five year average, W. W. BONNS (*Proc. Fruit Growers' Conv. Cal., 45 (1914), pp. 114-118*).—A progress report on a long-continued experiment being conducted at the California Citrus Substation with the view of determining the value of sweet, sour, and trifoliata orange stocks for the navel and Valencia oranges and the Eureka lemon. The Valencia orange and Eureka lemon are also being tested on pomelo stocks. The tests are being conducted on different types of soil.

No definite conclusions are drawn from the results to date. Attention is called to the fact, however, that the reputation of trifoliata stock for dwarfing trees does not hold good for all soils or all varieties. The behavior of the same

stock and variety varies on the light and the heavy soils. Trifoliata roots dwarf the lemon to an undesirable degree. In all cases there is a decided increase of the stock above ground when trifoliata has been used.

Improvement of lemon varieties by bud selection. A. D. SHAMEL (*Proc. Fruit Growers' Conv. Cal.*, 45 (1914), pp. 257-266, figs. 5).—A progress report on the author's work in bud selection (E. S. R., 32, p. 439).

As to the results secured in improving lemon trees, the author concludes in brief that in the experimental work and in the practical rebudding work carried out by cooperators "we have as yet to find a single exception to the rule that the unproductive and undesirable types of healthy trees can be successfully top-worked and replaced with productive and desirable types of lemon trees by rebudding."

The relation of washing to decay in Washington navel oranges; season of 1914-15. C. W. MANN (*U. S. Dept. Agr., Bur. Plant Indus., Relation of Washing to Decay in Washington Navel Oranges, 1915*, pp. 4).—The results of previous investigations of the Bureau of Plant Industry (E. S. R., 20, p. 43) have shown that washing even under the most favorable conditions is followed by an increase in the decay in the packed fruit. In the present paper the author describes an investigation conducted by the Bureau during the orange shipping season of 1914-15 to determine the relation of handling to the occurrence of decay resulting from the methods used in the washing and subsequent drying of the fruit. A comparison was made between fruit very carefully picked by the Bureau men with the same kind of fruit handled under ordinary commercial conditions. All of the fruit was washed in the ordinary machinery, a part being packed while still moist and wet and an equal amount of fruit thoroughly dried before packing. A part of the same fruit was packed without washing or brushing.

The data secured from these tests show that the percentage of decay in carefully handled fruit was increased from 1.8 per cent in the unwashed fruit to 3.4 per cent in the washed and thoroughly dried fruit and to 3.9 per cent in the washed fruit packed wet. In the ordinary commercially handled lots the average percentage of decay in the unwashed fruit was 8.3 per cent. Washing followed by thorough drying increased the decay to 11.4 per cent, and in the same fruit packed wet the average decay was 13.9 per cent. The difference in the percentages of decay developing in the wet and dry packed fruit was considerably greater during the period of cloudy or wet weather early in the season. The figures given are the averages for the whole season.

The work in general indicates that the losses from decay resulting from packing improperly dried oranges are directly in proportion to the care exercised in the methods of handling.

Experiments were made to determine the time required to dry the fruit under different conditions of temperature and humidity. The most rapid evaporation of the moisture of the fruit took place with dry air at a temperature of 130° F. The time varied approximately 11 minutes with an air blast having a temperature of 55° and a relative humidity of 70 per cent to about one minute with air at a temperature of 130° and a humidity of 14 per cent. In experiments conducted with two types of driers it was found that infection with blue mold may be increased if the dusty air from the packing house is blown on the fruit in the air blast. In an efficient system of drying the cost of heating air to a temperature of 130° should not exceed \$1 per car of packed fruit.

Some experiments in pineapple planting. S. M. CAPISTRANO (*Philippine Agr. and Forester*, 4 (1915), No. 2, pp. 45-50).—A number of cultural experiments and a variety test conducted by the author at the College of Agriculture are reported.

[Cacao experiments, 1913-14], J. DE VERTEUIL (*Bul. Dept. Agr. Trinidad and Tobago*, 14 (1915), No. 3, pp. 74-97, pls. 6).—A progress report for the year ended August 31, 1914, relative to manurial, shade, pruning, and natural yield experiments being conducted in a number of plantations in Trinidad (E. S. R., 30, p. 444), including also data on manurial experiments with cacao and rubber in Tobago.

The flower garden, T. W. SANDERS (*London: W. H. & L. Collingridge [1915], 2. ed., pp. 472, pls. 56, figs. 40*).—A revised and enlarged edition of the author's work which treats of the designing, formation, planting, and management of flower gardens, including the description and cultivation of all hardy and half hardy plants, trees, and shrubs adapted for outdoor culture in the British Isles.

FORESTRY.

Forest administration in the southern Appalachians, K. W. WOODWARD (*Proc. Soc. Amer. Foresters*, 10 (1915), No. 2, pp. 130-140).—A discussion of forest conditions in the southern Appalachians with special reference to modifications which will be necessary in order to make the forest policy which has been worked out for western conditions fit in the East.

Present condition of applied forestry in Canada, H. R. MACMILLAN (*Proc. Soc. Amer. Foresters*, 10 (1915), No. 2, pp. 115-129).—A review of forest activities and conditions in Canada with special reference to the work of administration, protection, reforestation, and other activities leading to forest conservation.

Sand dune reclamation on the coast of northern California and southern Oregon, F. B. KELLOGG (*Proc. Soc. Amer. Foresters*, 10 (1915), No. 1, pp. 41-64, figs. 2).—An account of methods employed in sand dune reclamation as carried out on an extensive scale for over 15 years near the Oregon line in California, with special reference to the application of the methods in similar sand dune areas situated on the Siuslaw National Forest, Oregon.

Notes on the relation of planting methods to survival, E. E. CARTER (*Proc. Soc. Amer. Foresters*, 10 (1915), No. 1, pp. 9-17).—The author here presents the results of a study of planting methods started in 1913 on the Harvard Forest, Petersham, Mass. The three methods employed consisted in brief of planting in a mattock hole, planting in a slit with the sod previously removed, and planting in a slit without removing the sod.

The experiment has not been conducted sufficiently long to arrive at any conclusion. The data thus far secured, however, show that the hardier species as a group are less affected by the different methods of planting than the more tender species.

A formula for normal growing stock in selection system forests, T. T. MUNGER (*Proc. Soc. Amer. Foresters*, 10 (1915), No. 1, pp. 18-21, figs. 2).—The author here presents a formula which is believed to be thoroughly applicable in preparing preliminary working plans for virgin forests where adequate yield tables can not be prepared.

A possible measure of light requirements of trees, W. W. ASHE (*Proc. Soc. Amer. Foresters*, 10 (1915), No. 2, pp. 199, 200).—The author is of the opinion that the relation between the cambium surface of the stem and the surface of the crown of dominant trees affords a reliable basis for measuring the light requirements of trees. By establishing this ratio between cambium surface and surface of the crown in stands at different ages and on different quality sites, either for the dominant trees or for the crown classes which receive direct light, series are obtained which, it is believed, should express the relative demands on light for a species at different ages.

A table is given showing the variation in this relation with age and quality site for dominant trees of *Pinus tæda*.

The construction of a set of taper curves, W. B. BARROWS (*Proc. Soc. Amer. Foresters*, 10 (1915), No. 1, pp. 32-40, figs. 5).—A discussion of methods in vogue in preparing tabulations and curves showing the taper of trees for a given species.

Reading and replotting curves by the strip method, W. B. BARROWS (*Proc. Soc. Amer. Foresters*, 10 (1915), No. 1, pp. 65-67, figs. 9).—A method of reading and replotting curves representing graphically values used in forest measurements is here described.

The clinometer on fire lookouts, D. BRUCE (*Proc. Soc. Amer. Foresters*, 10 (1915), No. 2, pp. 201-206, figs. 4).—The application of the clinometer to the location of forest fires from lookout points is described.

The invasion of a planted prairie grove, R. J. POOL (*Proc. Soc. Amer. Foresters*, 10 (1915), No. 1, pp. 1-8, pl. 1).—A discussion of changes in the flora in the prairie region of Nebraska as brought about by the establishment of forest plantations of considerable size.

Investigation into the retarding effect of lime on the growth of conifers, A. D. HOPKINSON and H. D. ELKINGTON (*Agr. Students' Gaz., n. ser.*, 17 (1915), No. 4, pp. 176-178).—An investigation was started at the Royal Agricultural College in 1914 to ascertain the effect of varying quantities of calcium carbonate on the growth and development of Douglas fir (*Pseudotsuga douglasii*).

The data thus far secured indicate that Douglas fir grows well in sandy soils with small amounts of calcium carbonate. Increasing quantities of calcium carbonate up to 8 per cent have a distinct retarding effect on its growth. Above 8 per cent of calcium carbonate some counteracting factor, whose influence has not yet been established, dominates this retarding effect of the lime.

A study of Douglas fir seed, C. P. WILLIS and J. V. HOFMANN (*Proc. Soc. Amer. Foresters*, 10 (1915), No. 2, pp. 141-164).—This comprises a progress report on a study of Douglas fir seed which is being carried out at the Wind River Experiment Station, Carson, Wash., with special reference to securing the best type of seed for artificial reforestation, and to determine what class of seed trees are satisfactory for the natural restocking of timber-sale areas. As a result of the data secured in 1913 and in 1914 from planting tests of seed of varying sizes and secured from various sources, a number of suggestions and rules are given for application to cone collecting and in the selection of seed trees for reforesting cut-over areas.

Douglas fir and fire, C. S. JUDD (*Proc. Soc. Amer. Foresters*, 10 (1915), No. 2, pp. 186-191).—This paper shows the influence of forest fires in creating favorable conditions for the development of Douglas fir stands. The most favorable effect of forest fires in this respect is the burning off of the humus so that the mineral soil is exposed. In this soil Douglas fir, with its vigorous reproductive capacity, regenerates itself to the almost complete exclusion of other competitive and dominating species.

The management of Engelmann spruce-alpine fir stands, J. W. SPENCER (*Proc. Soc. Amer. Foresters*, 10 (1915), No. 2, pp. 192-198).—An account of the plan of management of mixed stands of Engelmann spruce and alpine fir at the Battlement National Forest, Colorado.

Monterey pine, L. T. LARSEN (*Proc. Soc. Amer. Foresters*, 10 (1915), No. 1, pp. 68-74).—An account of Monterey pine with reference to its range and occurrence; climatic, soil, and moisture requirements; associated species; habit of growth; tolerance; rate of growth and longevity; yield; susceptibility to injury; reproduction; and management.

Eysenhardtia polystachya, the source of the true *lignum nephriticum mexicanum*, W. E. SAFFORD (*Jour. Wash. Acad. Sci.*, 5 (1915), No. 14, pp. 503-517, figs. 2).—In this article, which is based on a paper read before the Botanical Society of Washington, the author establishes the identity of *lignum nephriticum mexicanum*, a nephritic wood remarkable for the blue fluorescence of its infusion in spring water, and which was celebrated throughout Europe in the sixteenth century as a diuretic. It proves to be the wood of a leguminous tree (*E. polystachya*) occupying an extensive range in the interior of Mexico. The species is described in detail.

DISEASES OF PLANTS.

The investigation of physiological plant diseases, R. E. SMITH (*Phytopathology*, 5 (1915), No. 2, pp. 83-93).—According to the author the term "physiological" or "nonparasitic" disease has come into use to describe troubles due to an autogenous functional disturbance rather than to the presence of a foreign organism. The information regarding a number of these diseases is reviewed and the author concludes that there is no such thing as an established group of physiological or nonparasitic plant diseases for the kind of troubles which have been described. They are all considered more or less obscure diseases of unknown etiology as yet unaccounted for. He claims that the only positively known inciting factors in plant diseases, excluding direct traumatism, are parasites.

A suggestion of a new phase of the problem of physiological diseases of plants, C. B. LIPMAN (*Phytopathology*, 5 (1915), No. 2, pp. 111-116).—Largely upon the basis of the author's investigations on mottled leaf of citrus trees (E. S. R., 31, p. 450), he proposes as a justified theoretical consideration to connect certain functional troubles in plants known as malnutrition or as physiological diseases with a definite lack of the specific plant food element, nitrogen, in available or usable form.

Bactericidal products in healthy and diseased plants.—I, Healthy plants, R. J. WAGNER (*Centbl. Bakt. [etc.]*, 2. Abt., 42 (1914), No. 21-22, pp. 613-624, figs. 5).—This first report deals with the natural immunity of plants, detailing studies made with three different bacteria named.

It is stated that in healthy plants three classes of antibacterial products may be found, namely, agglutinin, tending to limit bacterial movement, lysin, tending to dissolve bacterial membranes, and substances limiting multiplication of spores and of bacteria possessed of resistant membranes. To these may be added as a possible factor a heightened acidity of the cell sap.

[Adaptive specialization of vegetable parasites], F. HESKE (*Centbl. Gesam. Forstw.*, 40 (1914), Nos. 7-8, pp. 272-278; 9-10, pp. 369-375).—The author reviews recent developments regarding biochemical phenomena noted in plants, and discusses, in connection with the probable activities of ferments as related to the specialization of certain parasitic organisms, the apparent possibilities as regards the gradual production of ferments adapted to this work.

Disease resistance in plants, O. APPEL (*Science*, n. ser., 41 (1915), No. 1065, pp. 773-782).—In this paper, which was presented as a lecture before a number of agricultural colleges in this country, the author points out various problems in connection with resistance to plant diseases, and states that while the present methods of combating diseases should not be abandoned, efforts should be made to find the causes of immunity, and after solving this question to determine without infection the disease resistant qualities in different varieties and individuals in order to establish the desired resistance and at the same time eliminate undesirable qualities.

It is believed that in working along this line the breeding of disease-resistant varieties can be best accomplished.

Some problems of plant pathology in reference to transportation, F. L. STEVENS (*Phytopathology*, 5 (1915), No. 2, pp. 108-110).—Attention is called to a number of questions relating to the development of diseases in fruits in transportation. Of some of these troubles considerable information is at hand, but it is stated that there is necessity for further investigations on those which rapidly develop on wilting or old products under unsuitable conditions of temperature and humidity.

Report of the division of botany, H. T. GÜSSOW (*Canada Expt. Farms Rpts.* 1914, pp. 831-849, pl. 1).—This report contains an account of administrative work in connection with the destructive insect and pest act and various specific diseases, experimental work in plant-disease control, notes on investigations in economic botany, and a report of St. Catharines field laboratory for 1913 (pp. 845-849), in which notes are given of a number of the more important diseases of apples, pears, quinces, cherries, peaches, and plums observed during the season.

Among the plant diseases investigated, considerable attention was paid to those attacking the potato, and a description is given of a black heart of potatoes, which resembles that described by Bartholomew (E. S. R., 30, p. 149), but which, in the present case, is attributed to frost injury. An account is also given of apple canker and silver leaf of fruit trees.

[Plant diseases in Southern Nigeria], C. O. FARQUHARSON (*Ann. Rpt. Agr. Dept. South. Nigeria*, 1913, pp. 41-55).—A presumably new root disease of Para rubber trees at Calabar was said to be distinct from each of two others due, respectively, to *Polyporus lignosus* (*Fomes semitostus*) and to *Hymenochaete noxia*.

Cocoa trees are affected near the forks by a trouble described as of unknown causation. A pathogenic but undetermined fungus attacks also the maturing pods. *Thyridaria tarda* is a very common saprophyte.

Cotton leaf curl has been studied and the main conclusions therefrom are given. The first-year hybrids of native American cotton were immune, resembling in this the American parents. The disease is suspected to be identical with mosaic disease of tobacco. An enzyme may be the cause of the trouble.

Cotton anthracnose (*Colletotrichum gossypii*) attacks most severely the native cotton, American cotton and hybrids being almost entirely immune. A spotting disease of bolls was ascribed to cool nights. A stem blackening disease is mentioned as of obscure origin. *Ramularia areola* and *Uredo gossypii* were very common on American cotton, but neither affected seriously native plants. Spraying for the control of cotton diseases is impracticable, and careful selection of seed from immune plants and government seed control are suggested.

Fungus disease of peanuts (*Cercospora personata*) was somewhat serious. Its severity depended apparently upon the kind of weather prevalent during the given season, possibly being conditioned by another disease of unknown but probably physiological causation, which is described as suggesting cotton leaf curl.

Two rust fungi from the Royal Botanic Garden, Edinburgh, M. WILSON (*Notes Roy. Bot. Gard. Edinb.*, 8 (1914), No. 38, pp. 219-221, pls. 2).—The author notes the discovery of *Puccinia prostii* attacking a bed of *Tulipa sylvestris* and doing considerable damage, the plants affected producing but few flowers. The rust was probably present on the plants in 1913 or even earlier.

Uromyces scillarum was found on leaves of *Muscari polyanthum*, which has not hitherto been recorded as attacked by this rust.

Both fungi are briefly discussed in these connections.

Ustilago vaillantii on *Chionodoxa luciliæ*, R. C. DAVIE and M. WILSON (*Notes Roy. Bot. Gard. Edinb.*, 8 (1914), No. 38, pp. 227, 228, fig. 1).—In March, 1913, *U. vaillantii* was found in the anthers of *C. luciliæ* in the Royal Botanical Garden, Edinburgh. The fungus was studied in this connection, but no information is yet available regarding the method of infection in case of this plant, or whether this may be brought about by use of spores of this fungus from anthers of *Scilla bifolia*, in which it commonly occurs.

The crown gall of alfalfa, O. T. WILSON (*Science, n. ser.*, 41 (1915), No. 1065, p. 797).—The author gives a brief account of certain facts observed in the life history of the organism *Urophlyctis alfalfæ*, the cause of crown gall of alfalfa. The presence of a plasmodium as the vegetative stage of the parasite and the entire absence of mycelium at any stage is said to suggest that possibly the organism should be removed from the genus *Urophlyctis*.

Gummosis of beets, G. ARNAUD (*Compt. Rend. Acad. Sci. [Paris]*, 160 (1915), No. 11, pp. 350-352).—A gumming disease of beet roots is described.

The causative organism, which is an intercellular bacterium, is said to be closely allied morphologically to *Bacterium mori*. The attack appears to be conditioned or favored by injury to the roots from cold, though several fungi are found on the exterior portions of diseased roots. The financial loss is due largely to the transformation of saccharose and the production of a gum which is difficult to eliminate.

Late blight of celery, H. L. REES (*Washington Sta., West. Wash. Sta., Mo. Bul.*, 2 (1915), No. 11, pp. 11-18, figs. 4).—A description is given of the late blight of celery, due to *Septoria petroselinii apii*, and notes are given on its life history.

In an account of spraying experiments it is stated that two applications of Bordeaux mixture completely protected the crop. However, as the season was considered exceptionally unfavorable to the blight, it was not concluded that two sprayings will always control the disease.

The effect of planting in single and double rows and of board *v.* dirt blanching was tested. Single rows and board blanching, by reason of securing greater aeration, reduced the amount of disease.

Eight varieties of celery were tested, and marked differences found in their susceptibility to disease. For the control of this disease the author recommends transplanting of only healthy plants, frequent rotation of crops, spraying with Bordeaux mixture, and planting the least susceptible varieties.

In addition to the above, attention is called to a physiological disease of celery, said to be due to an excess of moisture.

A bacterial disease of lettuce, NELLIE A. BROWN (*U. S. Dept. Agr., Jour. Agr. Research*, 4 (1915), No. 5, pp. 475-478).—A preliminary report is given of a bacterial disease of lettuce plants, which was first determined from diseased lettuce plants received in this Department in January, 1915, from Nairn, La. When received the plants were full grown, with some of the outer leaves shriveled and dried, while others were in a soft-rotted condition. The centers of the heads were sound, but between the center and these dead outer leaves were others affected in varying degrees.

A study of the diseased material showed the presence of bacteria in and between the cells. These have been studied and compared with various known organisms, and the author suggests the name *Bacterium viridilividum* n. sp. for this form, owing to its peculiar appearance when grown on steamed potato.

A review is made of the rather brief literature of the bacterial diseases of lettuce, none of which seem to be the same as that here described.

Some diseases of the potato.—IV, Late blight or Irish potato blight, ETHEL M. DODGE (*Agr. Jour. Union So. Africa*, 8 (1914), No. 2, pp. 205-211, figs. 6).—

Continuing previous work (E. S. R., 32, p. 342), Bordeaux mixture is found to be protective and to increase the yield of tubers if sprayed on when the plants are 6 in. high and two or more times thereafter at intervals of from 10 to 14 days. This, however, delays the ripening of the tubers.

Protective measures available include careful selection and handling of seed potatoes, burning of haulms, rotation of crops, and isolation from solanaceous crops which are susceptible to *Phytophthora infestans*. If the tops are attacked, fallen spores may be killed by spraying the ground.

Notes on the distribution and prevalence of three important sweet potato diseases, L. L. HARTER (*Phytopathology*, 5 (1915), No. 2, pp. 124-126).—According to the author the stem rot of sweet potatoes, due to *Fusarium hyperoxysporum* and *F. batatas*, is known to occur in New Jersey, Delaware, Maryland, Virginia, Alabama, Ohio, Illinois, Missouri, Iowa, Kansas, Oklahoma, Arkansas, North Carolina, Georgia, and Mississippi. The black rot, caused by *Spharomonema fimbriatum*, is reported as occurring in New Jersey, Delaware, Maryland, Virginia, Ohio, Illinois, Missouri, Iowa, Kansas, Oklahoma, Texas, Arkansas, North Carolina, Georgia, and Alabama. The foot rot, a comparatively new disease due to *Plenodomus destruens*, is reported from Virginia, Missouri, Iowa, and Ohio.

New light on curly top of the sugar beet, R. E. SMITH and A. BONCQUET (*Phytopathology*, 5 (1915), No. 2, pp. 103-107, figs. 3).—The authors record certain facts which recently came to light in the study of the curly top of the sugar beet. They have confirmed the investigations of Ball (E. S. R., 20, p. 954) and Shaw (E. S. R., 23, p. 557) regarding the relationship between the leaf hopper, *Eutettia tenella*, and the occurrence of the disease. A study of affected plants has shown definite lesions accompanied by an organism which agrees fairly well with *Bacillus dianthi*, previously described as the cause of the carnation disease (E. S. R., 8, p. 235).

The authors have not succeeded in producing the disease by inoculating plants with this organism, and it is not known whether or not it is the inciting factor causing and inhabiting the lesions. Further study on this disease is said to be necessary.

Sugar beet mosaic, C. O. TOWNSEND (*Science*, n. ser., 42 (1915), No. 1076, pp. 219, 220).—The author states that while this disease has been observed for a number of years, it has not hitherto been described. It is known to occur in the middle and western portions of the United States and appears to be increasing from year to year. In some commercial fields it is said to affect from 10 to 20 per cent of the stand and threatens to become a limiting factor in sugar beet culture in some areas.

The leaves of the affected plants are said to be mottled yellow and green. The spots are not always sharply defined, but usually shade into each other, giving the affected leaves a yellowish appearance. Only a part of the leaves on a beet are diseased, at least during the early stages of development. Affected leaves, if numerous, generally occupy only one side of the beet crown, normal leaves occupying the opposite side, giving the beet top a one-sided appearance. The shortened petioles give the leaves a dwarfed appearance, as in the case of curly top. The roots are said to be dwarfed and often hairy, further resembling curly top. While the two diseases are somewhat similar, they are easily distinguished from one another.

Tobacco root rot observations, W. A. BARNET (*Canada Expt. Farms Rpts.* 1914, pp. 1022, 1023).—In connection with investigations of tobacco growing, the author reports plats of Burley tobacco in which certain rows or portions of the field seemed to have their growth completely arrested. This dwarfed appearance of the plants was prevalent in the field, and, it is said, was produced by

a disease which had affected previous crops, but had not been definitely recognized. The disease is considered as having been caused by *Thielavia basicola*, and cooperative experiments will be made with the Wisconsin Experiment Station in trying to breed a disease-resistant strain of Burley tobacco.

A serious new wheat rust in this country, M. A. CARLETON (*Science*, n. ser., 42 (1915), No. 1071, pp. 58, 59).—The author reports the discovery of *Puccinia glumarum*, the yellow leaf rust of wheat, in a field of wheat at Sacaton, Ariz., by a party representing the Office of Cereal Investigations of this Department. About the same time the rust was reported on *Hordeum murinum* in southern California, and later was found in considerable abundance in various parts of Oregon and Washington and to some extent in Idaho, and a few specimens were taken at Bozeman, Mont., and Logan, Utah.

Control of stinking smut of winter wheat with formaldehyde, H. C. MÜLLER and E. MOLZ (*Fühling's Landw. Ztg.*, 63 (1914), No. 24, pp. 742-752).—Detailed results are given of several series of more recent tests (E. S. R., 32, p. 341) with formaldehyde alone and with copper sulphate in solutions for steeping seed wheat for protection against stinking smut, also regarding the value, in this connection, of paraformaldehyde, which proved to be injurious and not protective.

The rôle of sucking insects in the dissemination of fire-blight bacteria, V. B. STEWART and M. D. LEONARD (*Phytopathology*, 5 (1915), No. 2, pp. 117-123).—In a previous publication (E. S. R., 30, p. 650) the relation of the tarnished plant bug as a carrier of the causal organism of fire blight was pointed out. In the present paper an account is given of experimental work on young apple seedlings under cages, to which the following species of sucking bugs were transferred from near-by weeds: *Adelphocoris rapidus*, *Campylomma verbasci*, *Orthotylus flavosparvus*, and *Percilosecytus basalis*.

From the results of the experiments it appeared that all of the above-named species are capable of producing fire-blight inoculations when the causal organism is present, and that they are undoubtedly instrumental in spreading the disease.

Three strawberry fungi which cause fruit rots, F. L. STEVENS (*Science*, n. ser., 41 (1915), No. 1068, pp. 912, 913).—In a previous publication (E. S. R., 31, p. 645) the author called attention to the presence of a number of rots on strawberries in shipment.

In the present paper descriptions are given of a fruit rot due to *Patellina* sp., and another rot caused by *Sphaeronemella* sp., both of which have been found on market berries. The frequency of their presence is believed to render them of considerable economic significance. In addition, a black rot due to *Sphaeropsis* sp. is described.

A nasturtium wilt caused by *Bacterium solanacearum*, MARY K. BRYAN (*U. S. Dept. Agr., Jour. Agr. Research*, 4 (1915), No. 5, pp. 451-458, pls. 4, figs. 3).—A description is given of a bacterial wilt disease of nasturtium, first observed in the summer of 1914. The disease prevents blossoming, stunts the plants, and finally kills them. It is caused by *B. solanacearum*, and a cross-inoculation with a virulent strain from tobacco produced typical nasturtium wilt.

Cultivated ageratums and verbenas were also found susceptible to infection by this organism, the author having thus added another family of plants to those already known to be subject to attack.

Oak fungus or *Armillaria mellea* in connection with nursery stock, W. T. HORNE (*Mo. Bul. Com. Hort. Cal.*, 4 (1915), No. 4, pp. 179-184, figs. 3).—In continuance of previous contributions (E. S. R., 27, p. 450; 32, p. 241), the author states that *Armillaria* spots have come to be of exceedingly frequent occurrence

throughout the best fruit-growing sections of California, especially in the central and northern valleys, probably averaging at least one such spot for every 10 acres of mature bearing orchard. Small nurseries seem particularly liable to *Armillaria* trouble.

Young trees may carry the fungus undetected in spite of the utmost vigilance, on account of the detachment of the rhizomorphs, or these may be hidden within the ball of dirt left on the roots. When an infected tree is planted it is thought the fungus will so far resist any hardship as to outlive the tree. It is considered unsafe to use soil or plants not known to be absolutely free from this fungus.

Oak mildew, F. W. NEGER (*Naturw. Ztschr. Forst u. Landw.*, 13 (1915), No. 1, pp. 1-30, figs. 6).—This is a discussion of oak mildew (*Microsphaera ulmi quercina*) since its sudden appearance in western Europe in 1907, including its development, systematic position, morphology, physiology, pathology, hosts, winter habits, and means of control, concluding with an extensive bibliography.

Dry rot of telegraph poles, K. HAVELÍK (*Centbl. Gesam. Forstw.*, 40 (1914), No. 7-8, pp. 278-295, figs. 7).—Investigation of an extensive and often rapid decay of telegraph poles showed *Merulius lacrymans* to be the chief cause of the injury. This was more frequent and severe in case of double than of single uprights, and more particularly in case of the A form as compared with the H form poles. This is thought to be owing to the looser texture of the soil around the double poles, due to the larger holes necessary and to the greater difficulty and supposedly less need of thoroughly packing the soil around these poles. Compactness and moisture of the soil seems to be unfavorable to rapidity of underground extension in case of *M. lacrymans*.

ECONOMIC ZOOLOGY—ENTOMOLOGY.

A preliminary note on the food habits and distribution of the Texas horned lizards, W. M. WINTON (*Science, n. ser.*, 41 (1915), No. 1065, pp. 797, 798).—The author reports upon studies conducted with a view to determining the economic status of *Phrynosoma cornutum*, during the course of which 485 stomachs have been examined.

It is pointed out that while the area of distribution of this species extends from Kansas southward far into the Mexican table-land and westward into Arizona its area of greatest abundance is the north and south strip of Texas known as the Black and Grand prairies. It is stated that within this area, where conditions are at all favorable, the average number of horned toads is at least 30 to the acre. The stomach examinations show that the noxious insects consumed overwhelmingly outnumber the beneficial species.

Entomological yearbook.—Calendar for all insect collectors, edited by O. KRANCHER (*Entomologisches Jahrbuch. Kalender für alle Insekten-Sammler. Leipzig: Franckenstein & Wagner, vols. 19 (1910), pp. 208, pl. 1; 20 (1911), pp. 196, pl. 1; 21 (1912), pp. 200, pl. 1; 22 (1913), pp. 195, pl. 1, figs. 5; 23 (1914), pp. 211, pl. 1, figs. 8; 24 (1915), pp. 224, pl. 1, figs. 8*).—These handbooks contain much information of interest to the entomologist, particularly as relates to the collection of insects during the different months of the year.

Report to the entomologist of the Arizona Commission of Agriculture and Horticulture for the year ending June 30, 1914, A. W. MORRILL (*Ariz. Com. Agr. and Hort. Ann. Rpt.*, 6 (1914), pp. 9-47, figs. 16).—The first part of this report (pp. 9-26) deals with the inspection of plant, fruit, and seed importations; inspection of orchards and nurseries; insect control and eradication; interstate movement toward the standardization of nursery inspection certificates, entomological investigations, etc.

The second part (pp. 27-47) consists of notes on the important insects of the year. The deciduous fruit and vine pests mentioned are the southwestern green flea-beetle (*Haltica foliacea*) which was the most notable through its injury to apple trees and grapevines; the western rose chafer (*Macrodactylis uniformis*); the flower thrips, which was unusually destructive to late blooming varieties of peas, etc. The citrus pests briefly mentioned are the soft brown scale (*Lecanium hesperidum*), citrus thrips, and a species of cicada. The field crop pests mentioned include the western army cutworm (*Chorizagrotis agrestis*); a species of blister beetle (*Tegrodera erosa*), which appeared in alfalfa fields; the corn flea-beetle (*Chaetocnema ectypa*); and a species of bill bug (*Spicnophorus callosus*) which attacked corn. Among the pests mentioned as attacking vegetable crops are the melon aphid, grasshoppers, the harlequin cabbage bug, and a small black beetle (*Blapstinus pimalis*), previously unknown as a crop pest. The cotton or melon aphid was the most destructive cotton pest of the year. A species of Goldsmith beetle (*Cotalpa consobrina*) was notably abundant in southern Arizona and did much damage by stripping the leaves from cottonwood trees.

Report from the division of entomology for the fiscal year ending March 31, 1914, C. G. HEWITT (*Canada Expt. Farms Rpts. 1914, pp. 853-876*).—The first part of this report deals with the administration of the Destructive Insect and Pest Act under the headings of the new plant quarantine or fumigation stations, inspection and fumigation of imported nursery stock, field work against the brown-tail moth, 1912-13, importation of parasites of the brown-tail and gipsy moths, collection of parasites, colonization of parasites, *Apanteles* in Nova Scotia, and parasites of native insects. The parts which follow report upon the occurrence of and work of the year with the insects affecting cereals and field crops, fruit crops, forest and shade trees, domestic animals and man, and the garden and greenhouse, and with apiculture.

Observations on the biology of *Nematus erichsonii*, *Athalia spinarum*, and *Hylemyia (Anthomyia) antiqua*, V. A. LEVTEJEV (*Mat. po Izuch. Vredn. Nasček. Moskov. Cub., 5 (1914), pp. 94-111; abs. in Rev. Appl. Ent., 2 (1914), Ser. A, No. 6, pp. 372-374*).—A report of two years' observations of these pests in Petrovo-Razumovskoje, near Moscow.

Insect enemies of Sudan grass, W. NEWELL (*Texas Sta. Circ. 7, n. ser. (1915), pp. 5-18, figs. 6*).—A number of native insects have found Sudan grass (*Andropogon sorghum sudanensis*), a forage plant introduced into the United States by Piper from Khartum, Sudan, in 1909, to their liking. One class attacks the seeds during their development or after harvest, while another class attacks the growing crop and reduces the yield of forage.

Those belonging to the first-mentioned class are the sorghum midge (*Contarinia [Diplosis] sorghicola*), which is the most important enemy of the plant, due to its destruction of the seed before maturity, and the Angoumois grain moth. A report of studies of the sorghum midge, a pest which has for many years been familiar to growers of sorghum, milo maize, and all other crops of this family, by Dean, has been previously noted (*E. S. R., 23, p. 364*). The destruction of Johnson grass, which affords a constant breeding place for the pest, is thought to be the most vital step in the control of this midge. The Angoumois grain moth does not prevent the Sudan grass from making seed, but the adult moths deposit their eggs in the seed heads before the harvest, the seed thus becoming infested with larvæ, and the moths continuing to breed in the stored seed. It can be destroyed by fumigation, experiments having shown that carbon bisulphid used at the rate of 15 lbs. to 1,000 cu. ft. of space with an exposure of 12 hours did not affect the germination of the seed. The author emphasizes

the importance of immediately sacking up the seed, preferably in sacks of heavy cloth such as canvas, free from holes, so that moths can not get to the seed to start another infestation.

The insects mentioned as belonging to the second class include the conchuela (*Pentatoma ligata*) and grasshoppers. The conchuela, an account of which by Morrill has been previously noted (E. S. R., 23, p. 461), has become a pest in the area in which the sorghum midge is scarce or absent on account of insufficient moisture. Its sucking of the sap from either the stem or seed head results in a rapid wilting or burning of the infested plants and their heads. As yet large areas of Sudan grass have not been grown in the localities where the conchuela is at present abundant. Where grasshoppers appear in sufficient numbers to cause injury, the weed patches should be sprayed with a sweetened arsenical, care being taken to keep all stock from grazing on these patches until after several hard rains.

The insect enemies of the fig, F. PICARD (*Prog. Agr. et Vit. (Ed. l'Est-Centre)*, 35 (1914), No. 36, pp. 279-286, pl. 1; *abs. in Rev. Appl. Ent.*, 3 (1915), Ser. A, No. 1, pp. 10, 11).—A general account of eight of the more important enemies of the fig illustrated by a colored plate.

Notes on the development of *Bacillus pestis* in bugs (*Cimex lectularius*) and their power to convey infection, A. W. BACOT (*Jour. Hyg. [Cambridge] Plague Sup.* 4 (1915), pp. 777-792, pls. 2, fig. 1).—The author's conclusions are "that for a percentage of bugs (*C. lectularius*) and probably all newly hatched ones a meal of septicemic blood from a mouse dying of plague is fatal. Bugs which are not killed by the infecting meal are capable of carrying *B. pestis* and reinfesting mice after a period of 48 days' starvation. The development of *B. pestis* within the crop of bugs differs generally from that which takes place in the stomach of the flea in respect of its slower and looser growth, this limitation of activity being accompanied by and possibly due to the preservation of the structural character of the blood for many days after its ingestion into the crop.

"The absence of any definite valve between the pump and the crop, together with the looser nature of the growth within the bug, preclude the idea of such mechanical blockage as causes regurgitation and mouth infection by fleas. It may be surmised, however, that mouth infection, when not caused by accidental or other injury to the bug while feeding, may be due to interruption followed by a second attempt."

Natural enemies of the sugar beet leafhoppers in California, W. J. HARTUNG and H. H. P. SEVERIN (*Mo. Bul. Com. Hort. Cal.*, 4 (1915), No. 5-6, pp. 277-279).—In order to determine the percentage of parasitized leafhoppers (*Eutettix tenella*) 500 specimens, collected at King City on September 2, 1913, by sweeping with an insect net beet leaves showing a severe condition of "curly top," were placed in breeding jars and vials containing beet leaves and stems which served as food material. During the following three weeks twelve puparia of dipterous parasites which represent two new species described by F. Knab as *Pipnuculus industrius* and *P. ragabundus* were found at the bottom of the breeding jars and vials, together with twelve dead leafhoppers; four jassids were parasitized by a dryinid.

At least 3.2 per cent of the leafhoppers were parasitized during the season of 1913 by dryinids, which have been determined by Rohrer as *Gonatopus contortulus* and *Labeo* n. sp. Data relating to the parasitism of leafhoppers during 1914 are presented in tabular form. It appears that 33.6 per cent of leafhoppers were parasitized and in addition a fungus disease was observed.

A bibliography of seven titles relating to the subject is included.

Catalogue of recently described Coccidæ, V, E. R. SASSER (*Proc. Ent. Soc. Wash.*, 17 (1915), No. 1, pp. 25-38).—This fifth part of the catalogue previously noted (E. S. R., 28, p. 754) is thought to be fairly complete to November, 1914.

On the occurrence of an intermediate in *Aphis pomi*, W. F. TURNER and A. C. BAKER (*Proc. Ent. Soc. Wash.*, 17 (1915), No. 1, pp. 42-52, figs. 18).—A discussion of aphidid forms.

The authors conclude that "in these intermediates we have to do solely with transitional forms between more primitive conditions on one hand and more advanced conditions on the other. We feel confident also that all these intermediates are of equal value. The very fact that variants have been discovered in so many different species, having such diverse habits, seems to us to preclude the possibility that these arise from different fundamental causes. The only difference is that the forms in *A. pomi* and similar species and the intermediate sexuparæ of various Phylloxera are varying in one characteristic, the elimination of wings, while the virginoparous forms in *Phylloxera vastatrix* and in the Chermesinae are varying in two characters, the elimination of wings and the elimination of sexes."

Further studies of the embryology of Toxoptera graminum, W. J. PHILLIPS (*U. S. Dept. Agr., Jour. Agr. Research*, 4 (1915), No. 5, pp. 403, 404, pls. 2).—This paper supplements the general account of the development of the winter eggs of *T. graminum* given in the bulletin by Webster and Phillips, previously noted (E. S. R., 27, p. 859).

A catalogue of Portuguese aphidids, J. S. TAVARES (*Broteria, Ser. Zool.*, 12 (1914), No. 3, pp. 177-193, figs. 8; *abs. in Rev. Appl. Ent.*, 3 (1915), Ser. A, No. 2, p. 90).—Eighty-nine species are recorded together with their food plants and the localities in which they have been collected.

Ravages of the forleule (*Panolis piniperda*) in the Woleschna woods in 1913, NECHLEBA (*Vereinsschr. Forst, Jagd, u. Naturk., Prague*, No. 11-12 (1914), pp. 614-633, fig. 1; *abs. in Rev. Appl. Ent.*, 2 (1914), Ser. A, No. 7, pp. 483, 484).—The author discusses the ravages of the forleule or pine moth in the pine woods of Woleschna, in Bohemia.

Combating *Euxoa segetum*, ENIKIEV (*Zeml. Ghaz.*, No. 31 (1914), pp. 1026, 1027; *abs. in Rev. Appl. Ent.*, 2 (1914), Ser. A, No. 12, p. 695).—This cutworm was the source of great injury to winter-sown crops in the district of Borovitchee in the Government of Novgorod in 1913.

The morphology and biology of *Carpocapsa pomonella* and *C. funebrana* (*Trudy Bessarabsk. Obshch. Estest. i Lûbit. Estest.*, 3 (1911-12), pp. 129-134, pl. 1).—It is shown that the larvæ of these pests may be distinguished by their structure, color, and size. See also a previous note (E. S. R., 33, p. 155).

Descriptions of new North American Microlepidoptera, A. BUSCK (*Proc. Ent. Soc. Wash.*, 17 (1915), No. 2, pp. 79-94).—Among the species described that are of economic importance are the following: *Memythrus perlucida* reared from *Populus trichocapa*; *Psacaphora cambiella* reared from the cambium of *Salix* at Evaro, Mont.; *Recurvaria alnifrutella* feeding on the catkins of alder and hazel at Falls Church, Va.; *Dichomeris vacciniella* from cranberry at Pemberton, N. J.; *Sparganothis albicaudana* reared from leaf tying larvæ on maple at Notch, Pa.; *Tortrix (Cacœcia) lambertiana* on *Pinus lambertiana* at Oakland, Oreg.; *Marmara pomonella* reared from larva mining just under the skin of apple at Corvallis, Oreg.; *M. serotinella* reared from *Prunus serotina* at Falls Church, Va.; *Argyresthia castaneella* reared from the bark of chestnuts infested with *Sesia castanea* at Falls Church, Va.; *A. franciscella* from tips of cypress at San Francisco; *Zelleria haimbachi* reared from short needle pine at Wenonah, N. J.; *Bucculatrix ilecella* reared from *Ilex* sp., at Victoria, Tex.; and *Prodoxus barberella* from *Agave palmeri* at Ray, Ariz.

A comparative study on the losses to rural industries from malarial mosquitoes, J. K. THIBAUT, JR. (*Reprint from South. Med. Jour.*, 8 (1915), No. 3, pp. 195, 196).—A supplement to the paper previously noted (E. S. R., 33, p. 255), in which the author reports upon studies made at Scott, Ark. It is stated that *Anopheles quadrimaculatus* was taken in every house in which malarial cases were visited and that in every case a breeding place was found within 50 yds. of the dwelling. Anopheles were not found breeding in either foul or very muddy water.

On the occurrence of *Aedes calopus* (*Stegomyia fasciata*) in Russia, E. J. MARZINOWSKY (*Bul. Soc. Path. Exot.*, 7 (1914), No. 7, pp. 590-593; *abs. in Rev. Bact.*, 4 (1914), No. 5, p. 70).—The yellow fever mosquito is recorded by the author as occurring at Batum, where the winter temperature falls to as low as 6.6° C., and on the Caucasian coast, where it appears at the beginning of the summer and disappears in October. It appears that this mosquito passes the winter in the larval stage, living larvæ having been found in water at a temperature of about 5°.

Notes on two parasitic Diptera, A. B. GAHAN (*Proc. Ent. Soc. Wash.*, 17 (1915), No. 1, pp. 24, 25).—The author records the parasitism of a mantid (*Stagmomantis carolina*) by *Sarcophaga* (*Helicobia*) *helicis*, and the army worm (*Heliophila unipuncta*) by a tachinid, *Metachæta helymus*.

Medullary spots and their cause, J. G. GROSSENBACHER (*Bul. Torrey Bot. Club*, 42 (1915), No. 4, pp. 227-239, pls. 2).—This paper reports upon studies of cambium miners carried on in continuation of those previously noted (E. S. R., 24, p. 561).

In comparing the life history and morphology of the Prunus miner with that of *Agromyza carbonaria* recorded by Nielsen^a and that of *A. pruinosa* as described by Greene (E. S. R., 30, p. 855), the author finds that it represents a different species to which he gives the name *A. pruni* n. sp. "The egg stage of these cambium miners is very short, apparently less than three days, while the larval stage lasts at least eleven months. The pupal stage lasts perhaps about three weeks, and the flies apparently oviposit within two days after emerging from the puparia."

Observations on the length of time that fleas (*Ceratophyllus fasciatus*) carrying *Bacillus pestis* in their alimentary canals are able to survive in the absence of a host and retain the power to reinfect with plague, A. W. BACOT (*Jour. Hyg. [Cambridge] Plague Sup.* 4 (1915), pp. 770-773).—"Fleas (*C. fasciatus*) are able to carry *B. pestis* for periods up to 47 days in the absence of any host and subsequently to infect a mouse. Infected fleas, starved for 47 days and then placed upon a mouse, may not infect it for a further period of about 20 days. There is no reason to suppose that the positive results obtained in these few experiments represent the limit of time after which infection may take place, but indicate that plague infection may persist in fleas for one or two months in cool weather and, subsequently, give rise to an epizootic."

The fleas found on rats and other rodents, living in association with man, and trapped in the towns, villages, and Nile boats of Upper Egypt, A. BACOT, G. F. PETRIE, and R. E. TODD (*Jour. Hyg. [Cambridge]*, 14 (1914), No. 4, pp. 498-508, fig. 1).—This is a report on collections of fleas made during an investigation of plague conditions in Upper Egypt in 1912 and 1913.

Descriptions of Braconidæ, S. A. ROHWER (*Proc. Ent. Soc. Wash.*, 17 (1915), No. 1, pp. 55, 56).—*Allodorus tomosiæ*, a parasite of *Tomoxia lineella* at Falls Church, Va., and *Macrocentrus ægeriæ*, parasitic on (*Sesia*) *Ægeria castaneæ* at Greenville, S. C., are described as new to science.

^a *Zool. Anz.*, 29 (1906), No. 7, pp. 221, 222.

Preliminary note on *Bracon* sp., a parasite of the cotton bollworm, F. C. WILLCOCKS (*Bul. Soc. Ent. Egypte*, 6 (1913), No. 2, pp. 56-67; *abs. in Rev. Appl. Ent.*, 2 (1914), Ser. A, No. 8, pp. 507, 508).—An undetermined parasite of *Earias insulana* has been found by laboratory experiments to breed equally well on the pink bollworm (*Gelechia gossypiella*).

The white grubs of sugar cane in Queensland, A. A. GIRAULT (*Bur. Sugar Expt. Stas. Queenland, Div. Ent. Bul.* 1 (1914), pp. 11).—A popular account prepared for cane growers, and based upon work during a period of three years at the Sugar Experiment Stations in Queensland. A technical report will follow.

The date stone beetle, F. C. WILLCOCKS (*Bul. Soc. Ent. Egypte*, 6 (1913), No. 1, pp. 37-39; *abs. in Rev. Appl. Ent.*, 2 (1914), Ser. A, No. 8, p. 506).—The author has found a small scolytid beetle, thought to be *Coccotrypes dactyliperda*, in dates from Sharkieh Province.

"An infested stone is perforated by a small circular hole and a quantity of pale-colored dust, composed of excrement and matter excavated from the stone, may be observed inside the date itself. . . . One date stone was found to contain 9 beetles, 6 pupæ, and 24 larvæ of different sizes, besides ova. Of 244 stones from the 'Amry' dates only 3, or 1.2 per cent, harbored the beetle, while of the 398 'Aglawy' date stones examined 47, or 11.8 per cent, were infested."

On parasitic and other nematodes biologically associated with bark beetles, G. FUCHS (*Verhandl. Gesell. Deut. Naturf. u. Aerzte*, 85 (1914), II, pt. 1, pp. 688-692; *abs. in Rev. Appl. Ent.*, 2 (1914), Ser. A, No. 6, p. 375).—This paper deals with nematodes that are found associated with bark beetles, particularly with *Ips typographus* and the weevil *Hylobius abietis*. Some of the nematodes are true parasites.

Two blossom weevils (*Anthonomus pomorum* and *A. rubi*), A. TULLGREN (*Meddel. Centralanst. Försöksv. Jordbruksområdet*, No. 93 (1914), pp. 12, pl. 1; *abs. in Rev. Appl. Ent.*, 3 (1915), Ser. A, No. 3, pp. 106, 107).—A popular treatise on *A. pomorum* and *A. rubi*, their biology and remedial measures.

A hymenopteran parasitizing the oothecæ of a blattid, A. ALFIERI (*Bul. Soc. Ent. Egypte*, 6 (1913), No. 1, pp. 14, 15; *abs. in Rev. Appl. Ent.*, 2 (1914), Ser. A, No. 8, pp. 504, 505).—Two species of *Evania*, *E. lævigata* and *E. abyssinica*, are said to have been reared from *Stylopyga orientalis* that were kept under observation.

The North American fever tick: Notes on life history, E. C. COTTON (*Tennessee Sta. Bul.* 113 (1915), pp. 31-77, figs. 15).—A report of biological studies of the cattle tick conducted at Knoxville, Tenn., earlier reports relating to which have been noted (*E. S. R.*, 20, p. 1054; 26, p. 458). Recent studies of the biology of this tick by other authors, including Newell and Dougherty in Louisiana (*E. S. R.*, 18, p. 987), Hunter and Hooker in Texas (*E. S. R.*, 19, p. 664), Graybill in Alabama (*E. S. R.*, 28, p. 63), and Hooker, Bishopp, and Wood in Texas (*E. S. R.*, 27, p. 865) have been noted. The report is presented under the headings of life history, the engorged adult, preoviposition period, the female reproductive organs, rate of oviposition, fatal temperatures, the egg stage, the incubation period, overwintering eggs, the seed tick, longevity of seed ticks from overwintering eggs, and mortality of seed ticks from extreme cold.

The following is a summary of the more important results of these investigations, which, it should be pointed out, are based upon and apply particularly to conditions in Tennessee, which State lies on the northern border of the tick belt.

"The parasitic stages of ticks are little affected by changes in air temperature. These require, respectively, 7 to 9 days for seed-tick engorgement, 5 to

10 days for nymphal engorgement, and 4 to 14 days for the final, or adult, engorgement. The nonparasitic stages vary greatly with the season and temperature. The preoviposition period may last but 2 days in midsummer or it may be prolonged to 56 days in winter and spring. The oviposition period varies from 9 to 122 days under similar conditions. . . .

"The alimentary system of the tick consists of from 10 to 12 cæca, or blind sacs, which provide large storage capacity. Movement of the food particles within these cæca is accomplished by peristalsis. No waste materials are excreted by the adult tick after final engorgement. Such materials are stored in the renal sac and the Malpighian tubes, mostly in the form of crystals of uric acid, which remain there after death. . . .

"The rate of oviposition varies with temperature. The average daily rate for 26 engorged ticks kept in the incubator at 85° was 285 eggs, the extremes being 156.8 and 407.1 eggs, respectively. The average number of eggs produced by each individual tick was 2,113, varying from 967 to 4,071 eggs. The largest number produced within any 24-hour period by a single tick was 1,006 eggs.

"Engorged adult ticks exposed to temperatures of 24° or lower may be killed by freezing. Those under dry conditions will survive temperatures fatal to those under moist conditions, while partly spent females are more easily killed by cold than those that have not yet begun egg laying. Ticks protected by a covering of dry litter will survive very much more cold than those not so protected, but moist litter offers no protection at all.

"Eggs protected by the viscid secretion from the shell glands retain their moisture very much longer than those without it. Those eggs from which this coating has been washed are liable to absorb sufficient water to destroy the embryos, if they remain submerged.

"The incubation period of the eggs varies from 24 days, the record of a lot of eggs laid by ticks dropping from the host on July 5, to 252 days for eggs laid by ticks maturing September 20. Eggs laid by ticks dropping from the host before August 28 will hatch before winter, while of those laid by ticks dropping after this date a few may hatch the same season, the remainder going over until the following spring. Whether they will hatch then depends upon the effectiveness of the viscid coating of the eggs in preventing excessive loss of moisture. Probably many of the eggs exposed to extreme cold are destroyed. In our experiments all eggs exposed to 2° F. were killed. It is very difficult, however, to dissociate this effect from that of excessive drying during the long dormant season. . . .

"The six-legged seed ticks immediately after emergence are able, if necessary, to fast for several months while awaiting a host animal. Our record of greatest seed-tick longevity is 298 days. . . . Seed ticks hatching from eggs laid by engorged ticks dropping during July live longest, while those from September-maturing ticks are the shortest lived, the longevity in this case being about one-third that of those from July ticks. . . . The average longevity of seed ticks hatching from overwintering eggs is 94 days, while that of seed ticks from eggs hatching before winter is 176 days. This indicates a debilitating effect on the developing embryos, due to cold and drying during the long dormant season. Seed ticks are able to survive the ordinary winter temperature of the tick area, except along the northern border. A temperature of 4° F., however, is fatal to all seed ticks."

A table is appended which gives detailed information concerning the 2,315 engorged female ticks kept under outdoor conditions at Knoxville, on which the facts and conclusions reached in this bulletin are based.

A list of 15 titles of the literature referred to is appended.

FOODS—HUMAN NUTRITION.

Refrigerated meat, E. PERRONCITO (*Ann. R. Accad. Agr. Torino*, 57 (1914), pp. 214-217).—Information is given regarding the extent to which refrigerated meat has been used in Europe, and especially Italy, during the years 1907 to 1912.

Whey in infant feeding, A. W. BOSWORTH, H. I. BOWDITCH and B. H. RAGLE (*Amer. Jour. Diseases Children*, 9 (1915), No. 2, pp. 120-125).—Feeding experiments with an infant are described in which the child received an abundance of fat, sugar, and protein, the whey constituents being the only variable.

The results of these experiments are in agreement with those of other investigators, and indicate that a ration composed of pure materials—fat, carbohydrate, and protein—needs the addition of substances such as whey salts to promote the growth of the young. The work also seems to bear out the theory that creatin excretion is in some way related to growth, and to offer an explanation of the fact that the creatin excretion of growing infants varies from day to day.

The phosphoric oxid content of maize flour, J. McCRAE (*Jour. Hyg. [Cambridge]*, 14 (1914), No. 3, pp. 395-398).—To ascertain the loss of vitamin in the usual milling of maize meal or flour a number of milled samples of different grades of fineness were analyzed. The vitamin loss (assumed to be parallel to that of phosphoric oxid) was found considerable, though not so great as that resulting from the polishing of rice.

For experimental purposes the milling process was so altered that 96 per cent of the original grain (instead of from 84 to 89 per cent) was converted into fine meal passing a 30-mesh sieve. This meal was found to contain nearly as much phosphoric acid as the original grain. Feeding experiments with 6,000 laborers are in progress to determine the relative merits of the flours prepared by the new and old style methods of milling. No intestinal disturbances due to the use of the new type of meal have been observed thus far.

The author concludes that "fine white meal, produced after removal of the husk and a considerable proportion of the germinal portion of maize, is a defective foodstuff which may give rise to some form of deficiency disease; by grinding the maize in such a way that practically the whole of the grain is converted into fine meal this defect is remedied."

Atmospheric conditions in relation to bread making, J. E. WIELFAHRT (*New York: The Fleischmann Co.*, 1915, pp. 15, figs. 4).—This pamphlet, which is intended for commercial bakers, discusses the importance of and gives hints regarding the control of temperature and humidity to secure the best results in baking. An inexpensive moisture generator is described, as well as some measuring instruments.

War bread, E. FLEURENT (*Compt. Rend. Acad. Sci. [Paris]*, 161 (1915), No. 3, pp. 55, 56).—The author describes a method for improving the keeping quality of bread, the essential features of which are as follows:

A dough is prepared as usual, but the baking is prolonged to insure sterilization of the loaf. On removal from the oven the bread while still hot is wrapped in two thicknesses of paper and the wrapper sealed. The wrapped bread is then submitted to a second baking at a temperature of 120 to 130° C. for 15 to 20 minutes. It is said that bread thus prepared has been kept for a month and longer in damp cellars without deterioration.

The bread of the Kaingang Indians of Brazil, R. LIESKE (*Jahrb. Wiss. Bot. [Pringsheim]*, 53 (1914), No. 4, pp. 516-526).—The author reports a bacteriological and chemical examination of bread prepared by these Indians from matured and unripe corn by an acid fermentation process.

Honey as a food, B. C. ASTON (*Jour. Agr. [New Zeal.]*, 11 (1915), No. 1, pp. 48-52, fig. 1).—Data are given regarding the composition of honey. Honey is compared with other foods as to its fuel value, the ash it supplies to the diet, and its price per pound.

Note on vinegar, J. S. JAMIESON (*Analyst*, 40 (1915), No. 468, pp. 106, 107).—Comparative analyses are given of a vinegar prepared from malted barley and one prepared from malted maize. A vinegar prepared from germinated maize and pasteurized, the same vinegar before pasteurization, and an ordinary barley malt vinegar were also studied. The author concludes that the proteins and phosphates from malted maize are not so readily extracted by an aqueous infusion as in the case of malted barley.

[**Food inspection and analysis and other topics**], E. F. LADD and ALMA K. JOHNSON (*North Dakota Sta. Spec. Bul.*, 3 (1915), No. 19, pp. 305-336).—This bulletin contains the results of the sanitary inspection of dairies, bakeries, restaurants, and other places where food is prepared or sold; together with popular information regarding various pure-food topics. Data are given regarding the examination of a number of samples of foods, drugs, proprietary medicines, and toilet preparations. A report of the analysis of toilet soaps, by R. Hulbert, is included.

Principles of food preparation, MARY D. CHAMBERS (*Boston: The Boston Cooking-School Magazine Co.*, 1914, pp. XX+251, pl. 1, figs. 33).—A text-book of cookery in which the fundamental principles presented are illustrated by a large number of simple experiments as well as by recipes recommended for classroom work.

Analysis and cost of ready-to-serve foods, F. C. GEPHART and G. LUSK (*Chicago: Amer. Med. Assoc.*, 1915, pp. 83).—This publication reports a study of approximately 350 different portions or "orders" of food as served to patrons in a chain of restaurants operated in several large cities of the country. The bulk of the publication consists of tabulated data regarding each order. The figures given show the cost of each order; the weight of its food constituents; the total number of calories of energy furnished; the actual amounts and proportion of this energy supplied by the protein, carbohydrate, and fat constituents; the number of calories obtained for 5 cts.; and the cost of 2,500 calories of energy furnished by the portion. The tabulated data are discussed, and the introduction by G. Lusk considers somewhat at length the results of the investigations in their relation to some fundamental principles in nutrition.

An educational lunch room (*Housewives League Mag.*, 6 (1915), No. 3, pp. 13-17, figs. 3).—A description is given of a lunch room conducted by the Board of Health of New York City, for city employees. Menus and food costs are discussed.

Fitting out the fleet—provisions, S. MCGOWAN (*Navy Dept., Bur. Supplies and Accts.*, [Leaflet], 1915, June 22, p. 1).—Estimates are given of the amounts of different foods required to feed for 30 days from 1,000 to 9,000 men. The values for foods are in all cases "practically in agreement with the quantities actually expended during 10 months of the battleship cruise around the world." The leaflet bears the date June 22, 1915.

Mutual service, CAROLYN P. WEBBER (*Bedford, Mass.: Author*, 1915, pp. 112, figs. 33).—This book, which has been prepared for distribution by gas companies to consumers, describes various forms of gas cooking, heating, and lighting apparatus, and gives instructions for their care and operation.

The influence of food on metabolism, G. LUSK (*Jour. Biol. Chem.*, 20 (1915), No. 4, Proc., pp. VIII+XVII).—In this address the author reviews the results of a number of his experiments which have been noted from other sources, and coordinates these results with those obtained by a number of experimenters.

On the cholesterol content of the tissues of growing rats when under various diets, P. E. LANDER (*Biochem. Jour.*, 9 (1915), No. 1, pp. 78-96, figs. 11).—Feeding experiments with laboratory animals (rats) are described, which were conducted to determine the normal cholesterol content of the tissues of growing rats, and to obtain information as to whether the growing organism can manufacture cholesterol when deprived of that substance in the food. The normal standard quantity of cholesterol contained in the bodies of rats which were just beginning to feed themselves was 0.1467 per cent. From the results obtained the following general conclusions are drawn:

“A pure synthetic dietary is insufficient to enable ‘growth processes’ to go on in young rats, in other words the rats are starved on such a diet and neither cholesterol, cholesterol esters, nor lecithin appears to supply the deficiency. [A commercial meat extract which was tested], however, appears to have a beneficial effect in some cases, rats fed on a diet with this addition showing no eagerness to nibble their dead comrades.

“There is no evidence that the living organism can manufacture cholesterol, but on the other hand it is a substance which is strictly conserved and readily picked out from a diet in which it is present in only small quantities. When, however, it is present in large quantities in the food then the percentage in the body goes up considerably, but only a small quantity of that ingested is actually stored up.”

Contributions to the physiology of the stomach.—XIX, Reflexes from the intestinal mucosa to the stomach, E. H. BRUNEMEIER and A. J. CARLSON (*Amer. Jour. Physiol.*, 36 (1915), No. 2, pp. 191-195, figs. 2).—Experiments with dogs having intestinal and gastric fistulae are described, from which the following conclusions are drawn:

“Gastric juice, chyme, acids, alkalis, water, milk, and oil introduced into the small intestine inhibit gastric hunger contractions and gastric tonus for varying periods. This inhibition of these gastric hunger contractions and tonus is due partly to mechanical, partly to chemical stimulations of the intestinal mucosa. The chemical stimulation produces the greatest effect.

Animal calorimetry.—VII, The metabolism of a dwarf, F. H. MCCRUDDER and G. LUSK (*Jour. Biol. Chem.*, 13 (1913), No. 4, pp. 447-454).—The results are reported of a metabolism experiment made with a dwarf 17 years old suffering from infantilism:

“The basal metabolism was increased 6.6 per cent as a result of the ingestion of food, and this again was increased by 14.7 per cent when the boy was reading illustrated periodicals in bed. The protein metabolism yielded the normal proportion of 15 per cent of the total calories of heat production. Nothing abnormal could be detected in the metabolic processes of the individual, as determined from these calorimetric observations.”

Earlier experiments have been noted (E. S. R., 28, pp. 865-868).

Animal calorimetry.—VIII, The alleged influence of the adrenals on diabetic metabolism, G. LUSK and J. A. RICHE (*Arch. Int. Med.*, 13 (1914), No. 5, pp. 573-681, fig. 1).—Experiments with laboratory animals (dogs) are reported in which the total metabolism and the respiratory quotient were determined during the period of absorption of 50 gm. of glucose from the alimentary tract and also between 18 to 21 hours after this was administered.

Administration of epinephrine during these periods did not interfere with the metabolism of carbohydrates, and during the period of its administration the fraction of the total heat output furnished by carbohydrates was increased. From these experiments the conclusion is drawn that “the theory that epinephrine causes a production of sugar from fat, decreases the power of the organism to oxidize glucose through inhibition of pancreatic function, and

stimulates the thyroid so that protein metabolism is increased, is untenable in any of its particulars."

Animal calorimetry.—IX, The influence of meat ingestion on the amino acid content of blood and muscle, MARY B. WISHART (*Jour. Biol. Chem.*, 20 (1915), No. 4, pp. 535-537).—A large number of feeding experiments with laboratory animals (dogs) are reported which substantiate the conclusions of the author that amino acids do not accumulate in the muscular tissues, but are either immediately destroyed or else synthesized into new (body) protein.

Animal calorimetry.—X, The rate at which ingested glycocoll and alanin are metabolized, F. A. CSONKA (*Jour. Biol. Chem.*, 20 (1915), No. 4, pp. 539-554, figs. 3).—This paper reports the results of further feeding experiments with phlorizinized dogs. Using the amount of extra sugar eliminated in phlorizin glycosuria as an index to the rate of metabolism of amino acids, the results obtained indicate that the rates of absorption of iso-glycogenic quantities of glycocoll and alanin are practically identical with the rate of absorption and elimination of ingested glucose.

Animal calorimetry.—XI, An investigation into the causes of the specific dynamic action of the foodstuffs, G. LUSK and J. A. RICHE (*Jour. Biol. Chem.*, 20 (1915), No. 4, pp. 555-617, pls. 15).—Previous experiments by the authors are reviewed somewhat at length and a large amount of additional experimental data are included, which may be briefly summarized as follows:

"A dog, after undergoing prolonged confinement in a cage without loss of body weight, manifested a marked reduction in basal metabolism, recovery from this condition being brought about by exercise. After the ingestion of a cold solution of 70 gm. of glucose in 210 cc. of water a discrepancy was noted between the heat production as measured by the direct and indirect methods, this discrepancy extending over 3 or 4 hours after ingesting the material. The same phenomenon was noted when cold water was ingested, although to a lesser extent.

"After prolonged confinement in a cage without loss of body weight, a dog may manifest a marked reduction in basal metabolism. Recovery from this condition is achieved through exercise.

"Ingestion of a cold solution of 70 gm. of glucose in 210 cc. of water causes a discrepancy between the measurement of heat by the direct and indirect methods which may extend over 3 or 4 hours after taking the material. The heat production is increased in order to replace the heat abstracted by the cold solution. To a lesser extent the same phenomenon occurs when cold water is ingested. This explains the disparity between heat found and calculated after meat ingestion noticed in the second paper [E. S. R., 28, p. 866].

"Glycocoll 5.5 gm. increased metabolism 7.3 per cent at a time when alanin 5.5 gm. increased it 7 per cent, and when the two mixed together increased it 18 per cent. Therefore, when two amino acids are given together there is a summation of effect. Eleven gm. of the mixed acids caused the same increase in metabolism as did 50 gm. of glucose.

"Glycocoll 20 gm., containing 42 nutritional calories, increased the metabolism by 33.75 calories, or 33.7 per cent above the basal level; while 10 gm., containing 21 nutritional calories, increased metabolism by 16.7 calories, or 16.7 per cent. The increase is therefore proportional to the quantity ingested. The extra heat production after giving glycocoll is nearly equal to the energy content of the glycocoll administered.

"After giving 20 and 30 gm. of alanin the heat production rose in proportion to the quantity ingested. Extra heat was produced to an extent of 53 per cent of the energy content of the ingested alanin.

"When the action of glycocoll and alanin is compared, the quantity of extra heat produced is not found to be proportional to the quantity of sugar formed, but there is some evidence to indicate that one molecule of glycolic acid liberated from glycocoll has the same power to increase heat production as one molecule of lactic acid derived from alanin.

"When carbohydrate is transformed into fat there is a small exothermic elimination of heat, for which due allowance may be made by calculation.

"After giving glucose 50 gm. with glycocoll 20 gm., the increase in the metabolism was almost as great as the sum of the increases induced when each substance was given alone. Alanin 20 gm. followed the same law when given with glucose 50 gm. (This nullifies the authors' former opinion.)

"The influence upon heat production of 50 gm. of glucose, sucrose, and fructose increases in the order named, which accords with [other investigators]. . . . The increases in single hours may be over 30 per cent above the basal level.

"After giving 50 gm. of lactose to the dog there was no increase in metabolism or in the respiratory quotient.

"After giving 50 gm. of galactose there was little increase in metabolism or in the respiratory quotient.

"Ethyl glycolate is a poison.

"Ethyl alcohol in small amounts (5.8 and 9.4 gm.) increases the level of the basal metabolism and does not merely replace an isodynamic quantity of fat.

"The resultant of the effect on heat production of ingesting glucose and alcohol together is nearly equal to the sum of the effects which each would have produced alone. The carbohydrate respiratory quotient is greatly reduced.

"After giving ethyl lactate it is probable, though not certain, that lactic acid acts as a stimulus to higher metabolism.

"Administration of phlorizin to a fasting dog may cause an increase in metabolism of as high as 70 per cent above the basal value.

"Glucose 10 gm. or 70 gm. and fructose 10 gm. have no influence upon the level of heat production in phlorizin glycosuria.

"Glycocoll 12.5 gm. and alanin 20 gm. increase metabolism when they are given to a phlorizinized dog, though they are not oxidized and their energy content is eliminated in the form of sugar and urea in the urine. Since the maximal effect upon heat production coincides with the period of their maximal metabolism, and since evidence exists to show that amino acids themselves do not stimulate metabolism (nullifies former opinion) one may conclude that intermediary products such as glycolic acid or lactic acid provide the stimulus. These experiments afford conclusive proof of a true chemical stimulation of protoplasm within the mammalian organism, and offer a logical explanation of the specific dynamic action of protein."

Calorimetric observations on man, J. S. MACDONALD, F. A. DUFFIELD, and K. LUCAS (*Rpt. Brit. Assoc. Adv. Sci., 1914, pp. 238-241*).—The experimental work done by the committee in continuation of that previously reported (*E. S. R., 32, p. 257*) is reviewed briefly. Employing the respiration calorimeter, the authors have studied the heat production and respiratory exchange of a man performing different amounts of work upon a bicycle ergometer.

The energy metabolism of 10 hospital children, J. R. MURLIN and B. R. HOUBLER (*Amer. Jour. Diseases Children, 9 (1915), No. 2, pp. 81-119, figs. 10*).—Using the respiration incubator previously described (*E. S. R., 32, p. 860*), the authors conducted a series of experiments to study the energy metabolism of 10 hospital children of from 2 to 12 months of age, of which the nutritive condition varied from that of the last stage of marasmus to one of considerable overweight. The heat production was calculated both on the basis of weight and of surface area, and the approximate specific gravity was determined in an at-

tempt to secure a measure of the proportion of fat to active tissue. Full experimental data are reported from which the authors draw in part the following conclusions:

"The specific gravity, even if accurately measured, can not serve as a measure of the proportion of fat to active tissue. . . .

"The heat production for the sleeping period averages for the 10 children 2.7 calories per kilogram and hour. It is highest on this basis for the atrophic and underweight children and lowest for the fattest child. On the basis of a square meter of surface the heat production of normal children shows a decided increase from the early months (2 to 4) to the later months (6 to 12) of the first year. The average of all the 10 children is 39.7 calories. The average deviation from the mean heat production in all sleeping periods is about ± 10 per cent for each of the several formulas expressing the relation of surface area to weight."

Practically the same average heat production per unit of weight and per unit of surface was obtained when all the infants between 2 months and 12 months in this series and in the experiments of others (61 in all) were compared, i. e., 2.7 calories per kilogram and hour, 39.3 calories per square meter and hour.

"On the unit of weight all but 3 of the atrophic and underweight children (48 in all) lie above the line represented by 2.5 calories per kilogram and hour; all the normals (18) lie near this line; and all but 1 of the overweight infants (5) lie below the line. Two and one-half calories per kilogram and hour or 60 calories per kilogram and 24 hours may therefore be called tentatively the 'normal heat production' of recently fed, sleeping infants between 2 months and 1 year of age. Included in this figure is whatever dynamic action the foods themselves may have; otherwise the figure is minimal. Hard crying may increase the metabolism as much as 40 per cent; the requirement for growth and allowance for nonabsorption must be added. . . .

"There seems to be no sufficient reason . . . for estimating the food requirements of infants on the basis of surface area rather than on the basis of weight."

A calorimetric calibration of the Krogh bicycle ergometer, F. G. BENEDICT and L. E. EMMES (*Amer. Jour. Physiol.*, 38 (1915), No. 1, pp. 52-61, figs. 2).—A report of the calibration of an electric brake bicycle ergometer, which has previously been described by Krogh (*E. S. R.*, 30, p. 767).

The ergometer, placed in a calorimeter, was rotated from the outside by a motor. The heat developed, as measured by the calorimeter, was compared with the computed work done in sustaining various loads on a suspended balance pan. Tests were made at different rates of speed and with different weights on the balance pan. "These experiments showed that friction and other extraneous factors may be entirely neglected in using the Krogh bicycle ergometer and that the results obtained by calibration were within 0.5 per cent of theory."

ANIMAL PRODUCTION.

Further experiments on the inheritance of coat color in rabbits, R. C. PUNNETT (*Jour. Genetics*, 5 (1915), No 1, pp. 37-50).—Continuing work previously noted (*E. S. R.*, 28, p. 768), the author reports further experiments with rabbits showing the unexpected appearance of agoutis in litters from black parents. He also gives results of experiments showing that chocolate in the rabbit, as in the mouse, behaves as a simple recessive to black and that the chocolate series of colors runs strictly parallel with the black series. These data are interpreted on both the "presence and absence" and the "multiple allelomorph" hypotheses, but reasoning is advanced to show that it would ap-

pear premature to reject the former hypothesis for the latter until the possession of facts compels.

A bibliography of the literature cited is appended.

Studies on inbreeding.—VI, Some further considerations regarding cousin and related kinds of mating, R. PEARL (*Amer. Nat.*, 49 (1915), No. 585, pp. 570-575, fig. 1).—Continuing this series of studies (*E. S. R.*, 32, p. 665), the author gives coefficients of inbreeding for continued single and double cousin mating and uncle and niece mating, with hypothetical pedigree tables illustrating these kinds of breeding. Illustrating graphically these coefficients of inbreeding, together with those from the continued inbreeding of brother×sister and parent×offspring, it is seen that the curves fall into two pairs alike for brother×sister and the double cousins, and for parent×offspring and single cousin, except that the cousin curves lag one generation behind the others. The uncle×niece curve is the same as the single cousin curve. From data presented in this and former papers, it is seen that inbreeding of any type when continuously followed for about 10 generations results in within 1 or 2 per cent of complete "concentration of blood."

The author extends the table of general equations given by Jennings (*E. S. R.*, 32, p. 665) for coefficients of inbreeding after n generations of each particular type of mating.

An attempt to produce mutations through hybridization, F. N. DUNCAN (*Amer. Nat.*, 49 (1915), No. 585, pp. 575-582, fig. 1).—Crosses were made with mutant stocks of *Drosophila* with wild stock from many localities in the United States, from the West Indies, France, and Australia in order to discover, if possible, whether hybridization is an essential factor in the formation of mutant races. From 16,637 flies of the F_2 generation, 7 flies arose which varied from the normal type and bred true. Four of these seven cases arose from wild stock just received from Illinois, so it is thought that the characters found to be inherited were recessive in the wild stock and not due solely to the cross. This narrows the results to one mutant to every 5,545 flies, a ratio too wide to attribute hybridization as its cause.

In the light of these results, the author considers that mutations arise only through chance.

The nitrogenous metabolism products and their value in determining the digestibility of the proteins of feed stuffs, A. MORGEN, C. BEGER, and F. WESTHAUSSER (*Landw. Vers. Stat.*, 85 (1914), No. 1-2, pp. 1-104).—From their studies with sheep and swine to determine the magnitude of the error occasioned by the excretion into the alimentary tract and the voiding with the undigested food of certain nitrogenous products of metabolism consisting of the secretions of the gastroenteric canal (including the bile), together with epithelial cells with some proteins and some other nitrogenous compounds of a nonproteid nature, the authors conclude that a correction previously made, which amounted to 0.4 gm. of nitrogen per 100 gm. of digested organic matter, was not sufficient and that the figure should be increased to 0.85 gm. per 100 gm. of digested organic matter.

Importance of calcium and phosphoric acid in the animal organism.—III, Value of the principal phosphorus compounds to the ruminant, G. FINGERLING (*Landw. Vers. Stat.*, 86 (1915), No. 1-2, pp. 75-114).—Results of experiments in the feeding of casein, phytin, lecithin, nuclein, sodium nucleinate, and disodium phosphate in rations to lambs indicated that an average of 89.2, 90.83, 92.72, 90.92, 93.62, and 90.53 per cent of the P_2O_5 in the respective phosphorus-containing materials was retained by the animal body, while with goats the percentages were 89.46, 96.81, 84.64, 88.54, 90.18, and 90.23.

Previous work has been noted (*E. S. R.*, 31, p. 71).

Feeding of potato foliage, L. MEYER (*Mitt. Deut. Landw. Gesell.*, 30 (1915), No. 32, pp. 472-474).—An account of the use of potato foliage hay for cattle and sheep feeding in Germany. It is said to compare favorably with meadow hay, having a composition as follows: Dry matter 85.7 per cent, protein 11.8, fat 2.8, nitrogen-free extract 35.1, crude fiber 23, and ash 13. The starch value of meadow hay is given as 34.3 and of potato foliage hay as 34.2.

[**Analyses of feeding stuffs**], F. T. SHUTT (*Canada Expt. Farms Rpts.* 1914, pp. 109-119).—Analyses are given of the following feeding stuffs: Cottonseed meal, distillery and brewers' grains, dried distillery slop, oil cake, gluten meal, barley germ meal, veiny pea hay, vetch hay, cacao bean husks, wheat middlings, golden flax, bran, hull-less oats, molasses, molasses feed, molassine meal, corn fodder, and corn silage, and of mangels and carrots of various varieties.

[**Animal husbandry work**], E. S. ARCHIBALD ET AL. (*Canada Expt. Farms Rpts.* 1914, pp. 297-328, 400-408, 410, 411, 416-454, 457-472, pls 16).—Steers of various breeds and types were fed from 80 to 151 days, it being found that steers fed quickly gave a good margin of profit, that the dairy type of feeder may be profitably finished in from three to five months according to age, and that many steers slaughtered in November and December would pay profitable returns if fed a few months longer. In steer-feeding experiments to determine the effect of heavy and light feeding it was found that while the daily rate of gain was greater in the heavy-fed lots, yet their average cost per pound of gain was considerably higher and the greater profit was realized from the light-fed lots. Grain was profitably replaced by molasses when used in only a limited amount. Molasses appeared to have a more beneficial effect when fed to good stocker than to good butcher cattle getting the same amount of grain. Molasses showed a profit over a full-grain ration.

Eight steers fed 140 days and given freedom in box stalls made a gain of \$56.17 as compared with \$3.23 from eight steers tied. In a comparison of corn silage and dry corn fodder as roughage for fattening steers fed five months, the former made an average daily gain per steer of 1.86 lbs., the latter of 1.5 lbs. Four lots of steers fed 140 days, lot 1 receiving oat straw, mixed hay, oats, and barley, fed outside; lot 2 the same as lot 1, but fed inside; lot 3 the same as lot 1 with the addition of silage, and fed inside and tied; and lot 4 fed mixed hay, silage, roots, and grain (bran, peas, oats, and barley), fed inside, made average daily gains per head of 1.95, 1.93, 2.47, and 2.82 lbs., respectively.

In feeding steers outside during the winter it was found that 77.31 lbs. of dry matter was required to produce 1 lb. of gain, the steers making 0.29 lb. of gain per head per day. Three lots of steers fed 85 days, lot 1 outdoors with free run, lot 2 in a corral, and lot 3 in box stalls, made daily gains per head of 1.73, 1.55, and 2.67 lbs. at a cost of 9.47, 10.48, and 6.15 cts. per pound of gain for the respective lots. In another experiment it was found that corral steer feeding, even in spite of severe weather, may be profitable. Steers of good beef type made rapid and economical gains and good profits, but steers of dairy type made slower gains, costing more to produce, and were fed at a loss.

Three lots of steers fed 135 days, lot 1 receiving alfalfa, roots, and grain, and lots 2 and 3, green oat fodder in addition, made average daily gains per head of 1.6, 1.5, and 1.6 lbs. for the respective lots.

Methods of feeding the work horse, brood mare, and young colt are reported. In an experiment to determine the most economical means of handling and feeding the work horse in winter, four lots were fed as follows: Lot 1, oat straw, oat fodder, oats, and bran; lot 2, oat straw, mixed hay, oats, and ground flaxseed; lot 3, oat straw, mixed hay, oats, and bran; and lot 4, oat straw, alfalfa

hay, oats, and bran. The cost per horse per day was 16, 18, 15, and 17 cts. for the respective lots. The cost of growing a horse from weaning at five months to two years of age was \$33.17 and that of wintering an idle horse, \$9.17.

Four lots of 9 lambs each were fed 97 days as follows: Lot 1, clover hay and alfalfa; lot 2, mixed hay and corn stover; lot 3, timothy hay and roots; and lot 4, mixed hay, roots, and extra grain. They made average daily gains per head of 0.085, 0.065, 0.037, and 0.106 lb., costing 22.7, 29.6, 47.7, and 16.6 cts. to produce a pound of grain. Three lots of 31 lambs each fed 92 days, lot 1 receiving alfalfa hay; lot 2, mixed hay and corn stover; and lot 3, timothy hay and roots, made average daily gains per head of 0.2, 0.054, and 0.068 lb., costing per pound of gain 14 $\frac{1}{2}$, 28, and 22 cts., respectively.

In two years' lamb-feeding experiments four lots of lambs were fed 118 days as follows: Lot 1, clover hay, roots, and grain; lot 2, clover hay and grain; lot 3, timothy hay, roots, and grain; and lot 4, timothy hay and grain. They made average daily gains per head of 0.24, 0.21, 0.24, and 0.2 lb., costing per pound of gain 11.4, 11.15, 11.7, and 11.82 cts. for the respective lots. Clover hay surpassed timothy hay in economy of production. When roots are used a better daily gain is obtained, but not quite sufficient to produce any appreciable profit by using them.

In an experiment in wintering a breeding flock, three lots of ewes were fed as follows: Lot 1, alfalfa in an open shed; lot 2, alfalfa in the sheep barn; and lot 3, hay in the sheep barn. They made average total gains per ewe during the 81-day period of 26.88, 27.42, and 22.06 lbs., respectively. Four lots of 25 lambs each were fed 112 days as follows: Lot 1, oat straw and grain (oats and barley 1:1); lot 2, oat straw, mixed hay, and grain; lot 3, oat straw, mixed hay, grain, and turnips; and lot 4, oat straw, alfalfa, hay, grain, and turnips. They made average daily gains per head of 0.19, 0.26, 0.25, and 0.27 lb., costing per pound of gain 8.3, 6.75, 7.4, and 6.9 cts., respectively.

In a three years' experiment six lots of about 50 lambs each were fed as follows: Lots 1 and 2, alfalfa, grain, and roots; lot 3, alfalfa and roots; lot 4, alfalfa and grain; lot 5, alfalfa and screenings; and lot 6, alfalfa alone, lot 1 being composed of yearlings and the remaining five lots of lambs. They made average daily gains per head of 0.23, 0.29, 0.19, 0.24, 0.23, and 0.17 lb., costing per pound of gain 10.71, 7.58, 9.34, 8.32, 6.11, and 9.8 cts., respectively.

Two lots of eight sows each were fed during the winter season, lot 1 receiving a mixture of wheat bran and shorts and lot 2 the same, with the exception that one-third of this mixture was replaced by tankage. The tankage-fed sows did not consume as much grain as where no tankage was fed. The weights of the sows at the beginning of the experiment and after farrowing were approximately the same. The average weights of litters at farrowing, at four weeks of age and at eight weeks of age, were 2.44 and 2.42, 11.4 and 13.5, and 19.7 and 25.3 lbs. for the respective lots. It is concluded that, although tankage when fed in these proportions is an expensive feed, yet this difference in cost is counterbalanced by greater ruggedness of litters, lower percentage of mortality, and the increased weight of litters at eight weeks of age.

Two lots of seven pigs each were fed four months as follows: Lot 1 ground oats, feed flour, and mangels, and lot 2 ground barley, feed flour, and mangels. They made average daily gains of 0.6 and 0.67 lb. per pig, costing per pound of gain 4.66 and 4.03 cts., respectively. Two lots of four pigs each fed three months, lot 1 twice a day and lot 2 three times a day, made average daily gains per head of 1.13 and 1.1 lbs., costing 3.35 and 3.45 cts. per pound of gain, respectively.

From records kept of two sows and litters during two years it was found that it cost a total of \$15.50 per sow and litter to feed the sow and 10 pigs during the winter.

The results of an experiment to determine the effect of feeding rice meal to fattening hogs are given in the following table:

Summary of experiments in feeding rice meal to fattening hogs.

Lots.	Feed.	Cost per pound of gain.	Average weight per pig.			
			Average daily gain per pig.	Viscera.	Liver.	Heart and lungs.
		<i>Cts.</i>	<i>Lbs.</i>	<i>Lbs.</i>	<i>Lbs.</i>	<i>Lbs.</i>
1	Rice meal, skim milk, and mangels.....	6.30	0.75	22.31	2.54	2.09
2	Wheat shorts, skim milk, and mangels.....	4.30	1.09	23.44	3.41	2.44
3	Rice meal, wheat shorts, skim milk, and mangels.....	4.70	.92	19.70	2.88	2.11
4	Grain, wheat shorts, skim milk, and mangels.....	4.66	1.05	22.55	3.75	2.50
5	Rice meal, ground alfalfa, and mangels.....	8.18	.59	20.01	2.38	2.00
6	Wheat shorts, grain, ground alfalfa, and mangels.....	7.00	.91	24.17	2.54	2.38
7	Rice meal, dried blood, and mangels.....	7.92	.58	20.75	2.10	2.08
8	Wheat shorts, grain, dried blood, and mangels.....	6.03	.91	22.93	2.65	2.00
9	Rice meal, ground alfalfa, dried blood, and mangels.....	7.76	.68	23.15	2.67	1.55
10	Wheat shorts, ground alfalfa, dried blood, and mangels.....	6.12	1.00	25.55	3.22	2.37
11	Wheat shorts, boiled potatoes, skim milk, and mangels.....	5.18	1.03	27.90	3.17	1.55
12	Rice meal, boiled potatoes, skim milk, and mangels.....	6.75	.58	18.65	2.30	1.55
13	Rice meal, skim milk, and mangels.....	5.78	.75
14	Grain, skim milk, and mangels.....	4.47	1.22	21.45	2.60	1.85

Phosphorus metabolism of lambs fed a ration of alfalfa hay, corn, and linseed meal, E. L. ROSS, M. H. KEITH, and H. S. GRINDLEY (U. S. Dept. Agr., Jour. Agr. Research, 4 (1915), No. 5, pp. 459-473).—In connection with studies conducted at the Illinois Experiment Station to determine the influence of different quantities of protein upon the nutrition of young growing lambs, data relating to the phosphorus metabolism of the lambs when weighing, on the average, 115 lbs. were reported. Differences in the quantities of protein fed were necessarily accompanied by corresponding differences in the quantities of phosphorus ingested by the lambs.

Two 9-month-old lambs were chosen from each of three lots which had been fed rations consisting of alfalfa hay, shelled corn, and linseed meal. At the time of this experiment the concentrates of the ration for the low-protein lot consisted of 95 per cent of shelled corn and 5 per cent of linseed meal; for the medium-protein lot, 75 per cent of corn and 25 per cent of linseed meal; and for the high-protein lot, equal parts of corn and linseed meal. The lambs were put in metabolism cages and analyses made of all the feed consumed and of the excreta.

In analyses of the feeds it was found that there were marked differences in the percentages of the different forms of phosphorus occurring in alfalfa hay, corn, and linseed meal, and in the ratio of phosphorus to protein in these feeds. A large part of the phosphorus of alfalfa hay consisted of the acid-soluble inorganic form; that of corn was equally divided between acid-insoluble and acid-soluble, the soluble being largely organic; and that of linseed meal was largely in the acid-insoluble form, the soluble being about equally divided between inorganic and organic phosphorus.

It was found that upon the ration used the lambs excreted in the urine only from 0.2 to 0.5 per cent of the total phosphorus ingested. The forms of phosphorus excreted in the feces showed that marked qualitative and quantitative changes had taken place during the processes of digestion and metabolism. A large proportion of the acid-insoluble phosphorus of the feeds was converted into acid-soluble phosphorus, and a large part of the soluble organic phosphorus was also changed into acid-soluble inorganic phosphorus.

The results of this metabolism experiment, together with those of the main feeding experiment of 217 days' duration, indicated that the phosphorus requirement for the normal growth and fattening of lambs does not exceed 3 gm. per day per 100 lbs. of live weight. There was no evidence of correlation between the amounts of phosphorus retained in the body, on the one hand, and the amounts of phosphorus ingested, the amounts of protein ingested, or the body weights of lambs, on the other. Variations in the quantity of digestible protein consumed from 1.56 to 3.19 lbs. per 1,000 lbs. of live weight per day did not influence significantly the forms of phosphorus in the feces, the total phosphorus in the urine, or the total phosphorus stored in the animal body, expressed in percentage of the total phosphorus ingested.

Tensile strength and elasticity of wool, R. F. MILLER and W. D. TALLMAN (*U. S. Dept. Agr., Jour. Agr. Research*, 4 (1915), No. 5, pp. 379-390, pl. 1, figs. 4).—The apparatus and methods used in determining the tensile strength and elasticity of wool at the Montana Experiment Station are described.

Feeding the sow and the suckling pigs, D. T. GRAY (*North Carolina Sta. Circ.* 25 (1915), pp. 5).—A general discussion of methods of feeding and care of the sow and the suckling pigs under southern conditions, including data showing the cost of feed in raising four litters of pigs to the weaning age to have ranged from \$11.12 to \$13.78.

Soy bean pastures for hogs, D. T. GRAY (*North Carolina Sta. Circ.* 24 (1915), pp. 6).—This is a general discussion, based mainly on work previously reported (*E. S. R.*, 20, p. 1031; 25, p. 374).

Feeding skim milk, buttermilk, and whey to hogs, D. T. GRAY (*North Carolina Sta. Circ.* 29 (1915), pp. 5).—This is a general discussion, based mainly on results of experiments conducted at several of the experiment stations and previously reported.

Report from the poultry division, F. C. ELFORD ET AL. (*Canada Expt. Farms Rpts.* 1914, pp. 955-991, pls. 7).—The maximum and minimum, also the range and average, temperatures in poultry houses having various proportions of cotton and glass are given. Results of experiments indicate that for an 8 by 4 ft. colony house in the Canadian climate a suitable proportion of wood, glass, and cotton would be, estimating from the floor up, 15 in. of wood, 2 ft. of glass, and 3.5 ft. of cotton.

In an experiment to determine the number of eggs that would be fertilized with one mating only, five fertilized eggs appeared to be the maximum. In a fertility test following 12 hours' mating it was apparent that this method was more conducive to results than the one mating only proved to be. In trials to determine the increase of pen fertility after the introduction of the male, maximum fertility, 100 per cent, was reached in a pullet pen six days after mating, and occurred three times in a period of 21 days. The same fertility was reached in a pen of old hens on the eleventh day after introducing the male, but the fertility increased more rapidly and continued a great deal stronger in the pullet pen than in the pen of old hens. One male was also kept with 44 White Leghorn hens. Though the percentage of fertility was highest when only 56.8 per cent of the hens were laying, the total hatch was only 33.3 per cent. When

86.4 per cent of the pen were laying, the total hatch was 48.1 per cent and the fertility 87.7 per cent. In other tests without mating again fertility could not be traced in eggs laid after hens had been broody for any length of time.

In an experiment to determine the best method of cooling eggs in an incubator, the eggs in an incubator containing eight trays were cooled for a mere turning 5, 10, 15, and 20 minute periods. The tray that gave the best results was cooled as follows: First week, five minutes in the afternoon; second week, 10 minutes in the afternoon; and third week, 15 minutes in the afternoon. Cooling one tray for several hours proved detrimental.

In an experiment to determine the profit on ducks hatched in incubators, reared in brooders, and sold on the local market at from 10 to 12 weeks old, 3.18 lbs. of feed per pound of gain were required, the average weight at the end of 10 weeks being 4 lbs. 11.2 oz. per duck.

Shipping eggs for hatching by parcel post proved to be quite as safe as by express.

The value for poultry feeding of screenings, scalplings (chiefly broken and shrunken wheat and the larger weed seeds), wild buckwheat, "black seeds" (lamb's quarter, wild mustard, and tumbling mustard), and each of these three separately, was tested. The presence of the black weed seeds in the ration made it not only unpalatable, but unprofitable as well. Wild buckwheat, however, made a very desirable feed. The mustards and lamb's quarter proved unpalatable and unprofitable. Some birds died, but in no case did death result from "poison," but rather from malnutrition. In the birds that suffered most severely, as in the case of the mustards, upon return to a normal ration the rebound was very rapid. The mustards rather than being poisonous seemed to have a stimulating effect on the digestive organs.

Data on the cost and amount of feed, cost of producing 1 doz. of eggs, and fertility and hatchability of eggs set with White Leghorn hens and pullets and Barred Plymouth Rocks are given, also data on the temperature, amount of oil used, and average cost per chick hatched by four types of incubators. Some rations for various classes of poultry which have been found satisfactory are included.

The limitations of cotton-seed meal feeding in poultry, B. F. KAUPP (*North Carolina Sta. Circ. 27 (1915), pp. 14*).—This is a report of preliminary experiments to determine the point of limitation of the feeding of cotton-seed meal for the different purposes for which birds are fed. The results are summarized as follows:

"Cotton-seed meal in dry mash, constituting 10 per cent of the mixtures for laying and breeding stock for a space of 90 days, in 19 flocks of birds has shown no noticeable physical effect. They apparently eat it with relish. This mash is given along with a morning and evening scratch feed and acts only as an adjunct. Cotton-seed meal constituting 20 per cent of a fattening ration in seven tests proved unpalatable, and the birds having a tendency to become sick if it did not eat sufficient to make satisfactory gains, and in some cases actually lost weight when kept on it for a period of 18 days. In cram feeding of 12 birds, four, or 33½ per cent, were thrown completely off digestion, as evidenced by the food remaining in the crop. Three died and one later digested her food again. Twenty per cent cotton-seed meal in one cram test did not produce satisfactory gains, due to its ill effect, in this quantity, upon digestion. In two tests upon three Leghorns gossypol (*E. S. R., 33, p. 311*) apparently produced the same results as were noted in the cram feeding and other lots.

"In the trough feeding, which proved unsatisfactory, the maximum amount of cotton-seed meal consumed was slightly less than 1 oz. a day. In the cram-

ming work the maximum amount of cotton-seed meal was slightly in excess of 2 oz. a day. It was noted that birds of weak constitution and delicate appetite are the first to become affected.

"All through this set of preliminary tests it was noted that as soon as the quantity of cotton-seed meal consumed reached about 1 oz. or more per day they may become sick. A bird sick of cotton-seed meal will usually eat grain such as corn, wheat, or oats unless the effect be so aggravated that the food remains in the crop."

Bacterial infection of fresh eggs, DOROTHY W. CALDWELL (*Abs. in Science, n. ser., 42 (1915), No. 1079, p. 322*).—The results of a bacteriological study of fresh eggs conducted at the Rhode Island Experiment Station are given as follows:

"Of 2,510 fresh eggs from 65 hens, examined by the indirect method, 8.8 per cent showed infection in the yolk. None of 111 whites examined showed infection, while the yolks of the same eggs gave a percentage of infection (4.5) less than the average for the series (8.8). The percentages of infection obtained for individual hens per year varied between 2.8 and 15, the average being 8 per cent per year. No hen laid sterile eggs during a whole year. No correlation was observed between the percentage of infection for any individual and the degree of fecundity of that individual. Approximately the same amount of infection was found among fertile eggs (6.9 per cent infected out of 422 eggs examined) as among infertile (8.9 per cent infected out of 315 eggs). The infection of eggs in the degree made apparent by the present studies seemed to have no unfavorable effect upon their hatchability. Practically no difference between the percentages of infection of eggs from pullets and from hens in their second laying year was found. No definite seasonal variation was observed in the bacterial content of the eggs examined.

"No definite conclusions can be drawn from these studies regarding the influence of temperature upon the detection of infection in fresh eggs. From 57 infected eggs out of 737 examined in one of the series, 37 bacterial types were isolated, among which were 7 cocci, 11 motile rods, 18 nonmotile rods, and 1 spirillum. Control plates exposed under the hood in which the examinations were made yielded a variety of organisms, largely chromogens. This series, as a whole, did not resemble the series of egg organisms."

The study "indicated that the penetration of the shell after the egg had been laid, or infections during the passage of the egg through the cloaca, or during fertilization or while the albumin or the shell were being deposited, are uncommon. It seems more likely that infection of fresh eggs is largely due to occasional chance infections with harmless organisms taking place within the ovary of the fowl."

Bacteria in preserved eggs, MAUD M. OBST (*Abs. in Science, n. ser., 42 (1915), No. 1079, p. 320*).—Commercial and strictly fresh June eggs packed in solutions of 1:5, 1:10, 1:15, and 1:20 parts of commercial waterglass, and in saturated lime solutions were stored in the laboratory, barn, cellar, and at 34° F.

The temperature of 80° in the laboratory permitted rapid multiplication of bacteria in eggs. Of the eggs frozen in solutions some later thawed without breaking and at the end of the experiment showed no effects attributable to freezing. The bacterial content was uniform and fairly low.

The bacterial increase in commercial eggs in 1:10 waterglass was rapid, especially in the albumin, during the first two months of storage. The eggs stored in the cellar held a uniformly low bacterial content throughout the experiment. At 34° the eggs showed exceptionally low counts. Waterglass solutions contained practically no bacteria after five months of storage. The aver-

age bacterial content of the eggs in nearly every lime solution increased more rapidly than in waterglass.

The bacterial content of the albumin in most cases remained lower or equal to that of the yolks for 150 or 250 days of storage, then increased markedly and generally far exceeded that of the yolk.

From apparently good eggs were isolated *Micrococcus aurantiacus*, *Bacillus prodigiosus*, *B. subtilis*, *B. pyocyaneus*, *B. fluorescens liquefaciens*, *B. termo*, and *B. zopfii*. One decomposed egg contained *B. proteus* in large numbers.

DAIRY FARMING—DAIRYING.

[**Dairy husbandry**], E. S. ARCHIBALD ET AL. (*Canada Expt. Farms Rpts.* 1914, pp. 329-365, 369-375, 380-399, pls. 8).—Comparisons were made of the feeding value for dairy cows of molasses and molasses meal. It is concluded that molasses meals tend to increase the cost of milk production. The cost of production is lower with molasses, and this is more palatable and appears to be a better milk producer.

From tests with a mechanical milker it is concluded that even when the best methods possible were adopted, certified milk was an impossibility. Good pure milk was possible if special precautions were taken in the washing and sterilizing of the milker after each milking period. The machine apparently had no ill effect upon the cattle. It is estimated to have reduced the labor of milking 50 per cent, but, on the other hand, largely increased the labor of washing and sterilizing the utensils. The installation of the machine is deemed warranted in a herd of 15 cows or more. The machine appears to exert some influence in hastening the end of the lactation period.

It is concluded from records kept of a number of cows that the biggest profit-making cows are in general the largest producers, which consume the most feed at the highest cost. Three cows which received 1 lb. of grain for 2.25 lbs. of milk gave, during the period of the experiment (128 days), an average profit of \$15.50 each; three which received 1 lb. of meal per 4 lbs. of milk gave an average profit of \$10.67; while three which received 1 lb. of meal per 8 lbs. of milk gave an average profit of \$9.26.

From records kept of representative cows it was found that the cost of feed to produce 100 lbs. of milk ranged from 59 cts. to \$1.25 and that the annual profit on milk over the cost of feed ranged from \$8.28 to \$73.05 per cow. The total cost of feed for a mature bull for one year was \$57.01. The cost of raising heifers from birth to six months is given as \$35.47, the cost from three months to 15½ months \$52.99, and the cost from 16½ months to 28½ months \$22.02. In another test the total cost of raising a heifer to one year was \$34.45, the average daily gain 1.5 lbs., and the cost per pound of gain 6.3 cts.

Three lots of calves fed 48, 35, and 34 days, respectively, for veal, made average daily gains of 2, 2.1, and 1.5 lbs. per head, consuming 7.86, 7.3, and 6.16 lbs. of milk per pound of gain.

In bacteriological tests milk taken directly from the teat contained 1,587 bacteria per cubic centimeter; milk taken from the pail, 5,154 per cubic centimeter; and milk from the cooler, 10,987. It was further found that the number of bacteria in the air of the barn appears to correspond to a great extent with the number in the milk. It is concluded from these tests that quickness and simplicity in methods of handling milk reduce the risk of contamination, that air-borne organisms play a great part in milk contamination, and that special care should be taken to have the air in barns as free from dust as possible.

In making a ripened soft cheese of the Coulommier type, experiments to determine the proportions and renneting temperature most suitable show the

best results with fresh morning's milk, rennet at the rate of 3.6 cc. to 30 lbs. of milk, a starter (acidity 0.7 to 0.8) at the rate of 9 to 10 cc. to 30 lbs. of milk, a renneting temperature of the milk of 86° F., and a room temperature of 65 to 68°. Some cheeses were tried without starter but were unreliable. The cheeses stand heat better when the percentage of moisture in the atmosphere is low. In those which are set with starter the room temperature may be somewhat raised or lowered without injuring the products, though this variation is not desirable. Cheeses invaded by liquefying organisms may frequently be saved by exaggerated salting, but this depreciates the product considerably.

Prickly pears as a feed for dairy cows, T. E. WOODWARD, W. F. TURNER, and D. GRIFFITHS (*U. S. Dept. Agr., Jour. Agr. Research*, 4 (1915), No. 5, pp. 405-450, pls. 3, fig. 1).—In these experiments, conducted by the Dairy Division in cooperation with the Office of Farm Management of this Department at the South Texas Gardens, Brownsville, Tex., prickly pear was compared in feeding value with sorghum hay, sorghum silage, and cotton-seed hulls.

The grain mixture consisted of equal parts by weight of corn chop, wheat bran, and cotton-seed meal; the hay was sorghum hay of average quality, and the prickly pear was a very spiny two-years' growth. The prickly pear was singed in the field with a gasoline torch, then cut off near the ground, and hauled to the cow lot. After being placed in the mangers, the heavier stems were chopped into small pieces with a sharp spade or hoe. The average analysis of the prickly pear fed in these experiments was as follows: Water 91.3 per cent, protein 0.58, albuminoid protein 0.29, ether extract 0.12, nitrogen-free extract 4.67, crude fiber 1.16, and ash 1.76.

Prickly pear was found to be a very palatable feed for dairy cows, even when it formed the major part of the roughage ration, and 100 to 150 lbs. were consumed per cow per day. The prickly pear ration caused an increase in the quantity of milk produced, a decrease in the percentage of fat in the milk, and a decrease in the total production of fat. The reduction in the percentage of fat became more pronounced as the quantity of prickly pears in the ration increased.

Assuming prickly pear to have 10 per cent. sorghum hay 80, sorghum silage 25, and cotton-seed hulls 90 per cent of dry matter, and considering the nutritive values to vary in direct proportion to the content of dry matter, 1 lb. of sorghum hay was equal to 15.9 lbs. of prickly pear when that plant was fed in large quantities, and to 10.1 lbs. of prickly pear when it was fed in moderate amounts. One lb. of sorghum silage was equal to 2.6 lbs. of prickly pear, and 1 lb. of cotton-seed hulls was equal to 5.8 lbs. of prickly pear. When prickly pear in moderate amounts was substituted for a part of the dry roughage, it appeared to have little effect on the digestion of the other ingredients of the ration; when substituted in large amounts it depressed the coefficient of digestion, although not to any great extent.

As the result of maintenance trials conducted during these experiments, it is believed that mature Jersey cows can be maintained on a daily ration of 3.5 to 6 lbs. of sorghum hay, 60 to 100 lbs. of prickly pear, and 1 lb. of cotton-seed meal a day; or, with prickly pear as the sole roughage, about 110 lbs. of that plant and 2 lbs. of cotton-seed meal. Prickly pear alone did not make a satisfactory maintenance ration, but sustained life for a long time. One cow that was fed prickly pear alone for a period of 70 days lost 30.2 lbs. live weight.

The average coefficients of digestion in two trials with prickly pear as the sole ration was as follows: Dry matter 61.58, organic matter 67.21, protein 71.56, ether extract 65.88, nitrogen-free extract 71.55, crude fiber 42.98 and ash 38.37.

Palatability was apparently an important factor in feeding prickly pears as the sole roughage. One cow that ate prickly pear with relish did as well on the ration when that plant was the sole roughage as when some dry roughage was included. Another that ate prickly pear reluctantly lost in weight. In one case feeding prickly pear alone caused the formation of an obstruction in the intestine and the death of the animal. The feeding of prickly pear produced a highly colored butter, but had no appreciable effect upon the flavor or keeping quality of the milk. Prickly pear had a decidedly laxative effect on the cows, although there seemed to be no permanent ill effects even after long-continued feeding. The addition of 4 to 6 oz. a day to each cow of common salt had no appreciable effect upon the laxative property of the plant.

During an experimental period of 10 days cows receiving a heavy ration of prickly pear drank no water, those receiving a medium ration drank an average of 44.3 lbs. of water per day, while those on a roughage ration of sorghum hay drank a daily average of 95 lbs. As measured by milk production, cows fed prickly pear were more sensitive to sudden drops in temperature than those which received a dry roughage. The greater the quantity of the plant consumed the more sensitive the animal became. The prickly pear ration appeared to have no great influence upon the size and vigor of the offspring or upon the condition of the cow after parturition.

The cost of harvesting prickly pear depends largely upon local conditions. During these experiments it was found that the spines could be singed at a cost of about 50 cts. per ton.

There was no great difference between the spineless and the spiny varieties of prickly pear in composition, palatability, or feeding value. While the cost of harvesting the spineless was less than that of the spiny varieties, the latter yielded a greater tonnage to the acre and were not so subject to injury from insects.

It is concluded that prickly pear is a good and palatable feed for dairy cows. It is best to feed the plant in medium quantities, 60 to 75 lbs. a day to each cow. When fed in large amounts, 120 to 150 lbs. a day, it causes an excessive scouring and a very insanitary condition of the stable. On account of the high content of mineral matter, it is thought that prickly pear may be of special value as a supplementary feed for use with other roughages of a low mineral-matter content, such as cotton-seed hulls.

Standards for determining the purity of milk.—The limit of error in bacteriological milk analyses, H. W. CONN (*Pub. Health Rpts. [U. S.], 30 (1915), No. 33, pp. 2349-2395*).—The importance of a revision of the standard methods of milk analysis as published by the American Public Health Association is pointed out. This paper gives the results of tests conducted cooperatively by four of the large bacteriological laboratories in New York City, the tests covering a period of seven months and involving nearly 20,000 separate analyses by a variety of methods.

It was found that individual analyses under the best conditions are subject to considerable variation, so that no single individual count can be properly relied upon. The question of the exact composition of the media to be used is deemed of far less significance than that of the methods used in the manipulation.

The need of unifying laboratory methods was demonstrated. There were found to be wide differences in the analyses of duplicate samples, due chiefly to differences in laboratory technique, the more important being the following: (1) Shaking of the samples. Wide variations were found in the vigor and the extent of the shaking to which the samples of milk and the dilutions are subjected by the different laboratories. (2) Amount of dilution. The counts

from highly seeded plates are uniformly lower than the counts of the same milk from low-seeded plates. The best results are obtained only when the plates contain somewhere between 40 and 200 colonies. (3) Methods of counting. This has seemed to be the cause of the widest amount of irregularity. The greatest difference was associated with the use or nonuse of a counting lens, or with differences in magnifying power of the lens used. Further results show that the personal equation in counting is still a factor of very large importance. When the same plate is counted by two different laboratories the results are not infrequently 100 per cent apart, and occasionally more. Another factor modifying the counting is the method adopted by each laboratory of estimating numbers rather than actual counting. (4) Irregularities in samples from the same bottle of milk. Two samples taken from the same bottle of milk, even after thorough shaking, are by no means identical. This is due to the clumping of bacteria and to the fact that inasmuch as bacteria are not in solution, but are solid objects, they can not be expected to be uniformly distributed through the liquid. (5) In low counts variation between duplicate samples is sometimes considerable, due to the irregularity of the distribution of bacteria. In high counts variation in reports is also sometimes very great, due to excessive crowding and to methods adopted in estimating the number of colonies.

The extent of variation in the results obtained from the analysis of duplicate samples varies widely with the care that is taken in the laboratory technique. At first the causes of irregularity were sufficient to give results disagreeing as much as tenfold in the number of bacteria that would be reported from any sample of milk. After the laboratories had adopted methods of bringing about uniformity in technique so far as possible, the variations were very greatly reduced, the last tests showing that when sufficient care is given the variations need not be more than twofold. It is not possible to rely upon a greater accuracy than 100 per cent even when an average of more than one analysis is obtained, although most of the results fall considerably below this limit.

There is no essential difference in the results whether the milk dilution is directly inoculated into the Petri dish and the agar poured upon it or whether the milk dilution is inoculated into the melted tube of agar and subsequently poured into the Petri dish. When examinations of cream are made the plate inoculation is unreliable, and the inoculation must be made in the agar tube followed by thorough agitation.

Five days' incubation (48 hours at 37° C. and 72 hours at 20°) gives a very slightly greater count than a two-day incubation. A 24-hour count gives on the average about one-half as high numbers as a 48-hour count.

The results of the tests seem to warrant three broad grades, essentially the three grades that have been adopted by the commission on milk standards, but they are not as yet accurate enough to warrant a closer grading than the commission's grades.

The series of tests has proved that if a sample of milk can be put into iced water, containing floating ice, it may be kept for 20 hours with very little change in bacteria count. This makes it possible to keep samples sent to a laboratory for analysis for a number of hours without any fear of change in bacterial content, provided the samples are immersed in water containing floating ice.

It is said that in making a comparison of the bacteriological analysis by the plate count and the microscopic count, the latter should be a count of groups rather than individuals, plate colonies representing groups only. Considerable experience by the person making the count is needed to distinguish between bacteria and dirt particles, particularly when the milk contains minute micrococci. When the microscopic count is made by one who has had sufficient

experience, the group count agrees somewhat closely with the plate count—agreeing, indeed, about as closely as the plate counts of different laboratories agree with each other. Raw, fresh milk does not contain any appreciable number of dead bacteria which might disclose themselves to the microscope, but fail to grow in plates.

The direct microscopic examination of milk smears by the Breed method (E. S. R., 31, p. 372) will classify raw milk into grades A, B, and C with about the same accuracy and much more quickly than will the plate method of bacteriological analysis. It can not be used in the study of pasteurized milk, however, since it discloses dead as well as living bacteria, except as indicating when such milk has become old before it is pasteurized by showing large numbers of dead bacteria with small numbers by the plate method. The direct method might be of exceptional value applied at the dairy to guide the dairyman as to the general grade of the milk he is marketing. It may also be of great aid to the large dealer to enable him to determine promptly whether he is purchasing milk of A, B, or C grade. The possibility of quick results and ease of making the smears at the dairy or shipping station, subsequently sending them to the laboratory for microscopic examination, renders the method especially applicable at the dairy end of the line.

Smoothness and keeping qualities in ice cream as affected by solids, W. K. BRAINERD (*Virginia Sta. Tech. Bul. 7 (1915), pp. 154-159, figs. 9; Rpts. 1913-14, pp. 154-159, figs. 9*).—From a micro-photographic study of ice cream the author concludes that smoothness and keeping quality or stability of texture of ice cream are closely associated. Smoothness depends upon the amount and fineness of division of solids present other than those in true solution, within limits; that is, the smoothness depends upon the size and distribution of ice crystals, which in turn depend upon the number and nearness together of minute solid particles which interfere with crystallization and reduce the size of the ice crystal.

Colloidal solutions of solids other than fat are deemed best adapted to ice-cream making, and the finer their division and the more complete the emulsion of the fats the better. The homogenizer has its application in this respect.

The keeping qualities of ice cream apparently depend upon the stability of the "mix." The keeping qualities of ice cream made from a given mixture will depend upon the disposition of the solids in that mixture to separate from the liquid, which in turn depends upon the fineness of division of the solids. The finer the division the better the keeping qualities up to the point at which the solid merges into a true solution.

VETERINARY MEDICINE.

Studies in acid-fast bacteria, I-X, A. I. KENDALL, A. A. DAY, and A. W. WALKER (*Jour. Infect. Diseases, 15 (1914), No. 3, pp. 417-471*).—The first of these studies is on the metabolism of saprophytic human tubercle bacilli in plain, dextrose, mannit, and glycerin broths. "Young, rapidly-growing tubercle bacilli appear to be, in part at least, nonacid-fast. The strain of avirulent tubercle bacilli studied here exhibit the Theobald Smith reaction characteristic of the growth of human tubercle bacilli in glycerin broth. Neither dextrose, mannit, nor glycerin appears to exert any marked sparing action for the protein constituents of ordinary media. Ammonia accumulates rather rapidly during the first, second, and third weeks of growth of tubercle bacilli in plain, dextrose, mannit, and glycerin broths, followed by a definite well-marked recession, during which this ammonia detectable in the media gradually diminishes in amount. The cause of this recession is unknown."

The second study deals with the metabolism of certain rapidly-growing human tubercle bacilli in broth free from lipoids and fatty substances. "In order to determine what part, if any, these lipoidal substances in the amounts in which they occur in ordinary media might play in the metabolism of tubercle bacilli, media were made up from ingredients in which these substances were definitely and quantitatively eliminated. . . . In glycerin broth, after a slight initial increase in ammonia amounting to about 2 per cent of the total nitrogen of the medium, the ammonia appears to decrease in amount, so that at the end of the experiments it is less than that contained in the uninoculated media. At the end of the second week the glycerin broth cultures of both strains of the tubercle bacillus were found to be slightly viscid, and by the end of the fourth week this viscosity was very marked. The reaction of the medium to phenolphthalein becomes progressively alkaline in spite of this decrease in ammonia. . . . It is conceivable that at least some of this ammonia is tied up in the bodies of the bacteria, and inasmuch as the organisms studied in this connection form firm tenacious pellicles, leaving the medium beneath them perfectly clear and free from bacteria, it was a comparatively simple matter to make a determination of the total nitrogen of the clear underlying broth. . . . The results show that a very considerable proportion of the total nitrogen in the medium is, apparently, tied up in the bodies of the bacteria. . . . While these experiments do not by any means prove that the substance or substances conferring acid-fastness on these organisms are derived from protein derivatives alone, yet it would seem that an experiment of this sort carried out under similar conditions, with especial emphasis on the fat and wax content of the organisms, would throw some definite light on the physiology of the formation of fats and waxes from protein."

The purpose of the study on the metabolism of the bacilli in a modified Uschinsky medium was to determine the cause of the recession of ammonia by the old cultures of avirulent tubercle bacilli employed in the second study with media of very simple composition. "For the purpose of this investigation a medium was made consisting of 4 gm. of asparagin, 2 gm. of disodium hydrogen phosphate, and 5 gm. of NaCl to the liter of distilled water as a basis. This medium was divided into three parts, to one of which was added 1 per cent of dextrose, to a second 1 per cent of mannit, and to a third 3 per cent of glycerin, as additional sources of carbon. They were then sterilized under parallel conditions in 100 cc. amounts. . . . An attempt was made to grow the organisms in the asparagin solution without any additional source of carbon, but this was unsuccessful. . . . The determinations were made in duplicate at weekly intervals for six weeks, and, with the exception of glycerin, the same recession of ammonia appears as was noted in the previous experiments. The glycerin does not show this recession. The extent of the recession was somewhat less marked than in peptone-containing media, but the growth, it should be noted parenthetically, was much less luxuriant. . . . Inasmuch as these organisms undoubtedly derive their nitrogen from the nitrogen of the asparagin, it might be assumed that the acid formed was due to the removal of the basic group of the asparagin. There is a certain amount of evidence in favor of this supposition, for the organism in question would not develop in this asparagin solution without an additional source of carbon. . . . At the same time the breakdown of asparagin, as measured by the increase in ammonia, was so great that it would be unjustifiable to assert that these substances exert a sparing action for the nitrogen. The extent of the breakdown of asparagin was, roughly, the same in each of these media. Although the maximum degree of nitrogen metabolism was apparently not reached even at the end of six weeks in the glycerin medium, at the end of four weeks, generally speaking, the maximum

growth was reached in the other media." The tubercle bacilli during the last three weeks of growth were completely acid-fast.

"One of the noteworthy changes produced in the media by the growth of the organisms in the asparagin medium was the development of a mucinous-like substance which was apparent even at the end of the first week. By the end of the second week it had apparently reached its maximum, although it persisted throughout the course of the experiment. It was possible to draw out the medium in long and viscid strings by touching it with a platinum needle. Although the medium underlying the pellicle of the tubercle bacillus exhibited this mucinous change most strongly, the organisms themselves were also somewhat mucinous in character. This viscosity was most marked in mannit, considerable in dextrose, and relatively slight in glycerin. . . . It is conceivable that the three phenomena, the decrease in weight of the tubercle bacillus pellicle, the decrease in antigen content, and the decrease in vegetative activity, as shown by the ammonia curve, are parallel phenomena, and the cause of the decrease in each instance is closely associated with the recession of this vegetative activity."

The metabolism of the bacilli in media with inorganic salts as sources of nitrogen, was taken up in the fourth study. It was found that by growing a strain of human type tubercle bacilli in "a medium of known and very simple composition, consisting essentially of diammonium-hydrogen-phosphate, as a combined source of nitrogen and phosphorus, and dextrose, mannit, and glycerin, respectively, as sources of carbon, at the end of two weeks, 4.2 mg. of nitrogen, that is to say, 10 per cent of the total nitrogen of the uninoculated medium, has been so changed by the growth of this organism that it can not be recovered as ammonia. This loss of ammonia is most plausibly explained on the assumption that it has been built up into the bodies of the newly developed bacteria. At the end of four weeks, between 40 and 50 per cent of this 'lost' nitrogen has reappeared in the clear medium underlying the pellicle of the tubercle bacilli in such a form that it can again be determined as ammonia. The period during which the disappearance of nitrogen from the culture fluid is the greatest corresponds with the period of maximum vegetative activity in the culture. Coincidentally with the reappearance of this nitrogen, which can be detected as ammonia in solution, there are evidences of a cessation of vegetative activity. This strongly suggests that the reappearance of this ammonia is associated with a certain amount of autolysis of the bodies of the bacteria."

In the fifth study, the metabolism of "lepra bacillus," grass bacillus, and smegma bacillus in plain, dextrose, mannit, and glycerin broths was considered. It was found that "the metabolism of the smegma and grass bacilli resembles that of the rapidly growing human tubercle bacilli, described previously, in two important particulars; neither dextrose, mannit, nor glycerin exhibits any appreciable sparing action for the protein constituents of the broth, the amounts of ammonia produced being practically the same in these media as in plain broth; and their cultures present a gradual increase in proteolysis to a maximum which is followed by a clearly defined recession of the metabolism indicated by a gradual decrease in the ammonia content. The 'lepra bacillus' does not present this metabolic phenomenon. This would suggest that this bacillus was entirely distinct in its cultural relationships from the grass and smegma bacilli, which follow more closely the metabolism of the tubercle bacillus."

As a result of the sixth study on the occurrence of a soluble lipase in broth cultures of tubercle bacilli and other acid-fast bacteria, it was determined that

"a variety of acid-fast bacteria, including various strains of the human tubercle bacillus, the bovine, and avian tubercle bacilli, as well as the leprosy, smegma, and grass bacilli, form lipase during their growth in glycerin broth. The lipase is present in the medium free from the bacteria. The lipase resists an exposure of 15 minutes to 100° C. in the moist state without appreciable diminution in its activity. The lipase formed by these organisms appears to be non-diffusible, at least in an active state, through either agar or a collodion membrane."

In the seventh study on the relative activity of the soluble lipase and lipase liberated during autolysis of certain rapidly-growing tubercle bacilli, it is stated that "the observations appear to justify the conclusion that certain acid-fast bacteria grown in nutrient broth, with dextrose, mannit, and glycerin as additional sources of carbon, produce an active lipase which appears in solution in the various culture media. The bodies of the bacteria, freed from adherent culture media and soluble lipase by thorough washing, also contain an active lipase, probably liberated as the bacteria underwent autolysis. The lipase in solution appears to be either greater in amount or more active than that contained in the bacteria freed from the culture medium. It can not be stated whether the lipase free in the culture media is freed as the result of autolysis of the bacterial cells (endolipase), or whether it is secreted by the bacteria as an exolipase."

In the eighth study on the specificity and thermostability of the lipase developed during the growth of a rapidly-growing tubercle bacillus in media of varied composition it was concluded that "a rapidly-growing strain of the human tubercle bacillus produces a lipase which appears to be qualitatively the same when it is grown in media varying in composition from one consisting essentially of ammonium chlorid, ethyl alcohol, Na_2HPO_4 , and NaCl to the extremely complex nutrient meat-juice-peptone broth ordinarily used for bacterial cultures. The lipase observed in the simplest media acts on various esters, irrespective of the nature of the carbon compound of the medium in which it is developed. For example, the lipase developed in the $(\text{NH}_4)_2\text{HPO}_4$ mannit medium acts on triacetin and castor oil as energetically as on ethyl butyrate or other simple esters. That is to say, the lipase developed in the simplest medium acts even on a complex glycerid. This lipase appears to be thermostable whether it is tested in the simplest media or in the most complex. The activity of the lipase appears to be roughly proportionate to the relative luxuriance of the growth of the tubercle bacillus."

By the ninth study, a comparison of the curves of lipolytic activity and proteolysis of certain rapidly-growing human tubercle bacilli in media of varied composition, it is shown that "the period of maximum vegetative activity of broth cultures of certain avirulent, rapidly-growing tubercle bacilli, as measured by ammonia formation (proteolysis), appears to coincide with the period of maximum lipolytic content of these cultures, as measured by their action on ethyl butyrate. Both ammonia production and lipolytic activity are extremely slight during the first day's growth of these organisms, and increase, roughly, proportionately to their respective maxima. There is a noteworthy recession of both factors after this maximum is reached. These experiments appear to warrant the assumption that the organisms studied excrete a soluble, active lipase during the period of active development; for if autolysis alone were responsible for the lipolytic activity observed in these cultures, it should increase as autolysis proceeds."

The tenth study was a comparison of the curves of lipolytic activity and proteolysis of certain acid-fast bacilli in nutrient broths. It showed that "in general, with the exception of the 'lepra bacillus,' the acid-fast bacteria dis-

cussed show a parallelism in their curves of lipolytic activity, as measured by the liberation of acid from ethyl butyrate and their curves of proteolysis. This parallelism is discernible in cultures in plain, dextrose, mannit, and glycerin broths."

The antigenic properties of glycoproteins, C. H. ELLIOTT (*Jour. Infect. Diseases*, 15 (1914), No. 3, pp. 501-517).—The results of anaphylaxis, precipitation and complement fixation tests of glycoproteins (ox tendon mucin, ox submaxillary mucin, and swine stomach mucin) show that the glycoproteins are capable of acting as antigens but are not so powerful as simple proteins. This is in accordance with the findings of other investigators with other compound proteins, as well as with simple proteins modified by the addition of various substances.

"Each mucin gives rise to an antiserum that reacts with itself in comparatively high dilutions; with the blood serum of the same species to a less degree; and with the other mucins almost as well as with the blood serum. The reaction with the other mucins is independent of species and the antiserum does not react with the blood serum of the different species.

"The present study does not throw any light on the nature of the union of the protein and carbohydrate components of the glycoproteins, excepting that it demonstrates that the antigenic properties of this class of compound proteins are different from the antigenic properties of another common class of compound proteins, the 'nucleoproteins' which as such are said to produce specific antibodies for themselves. While the antibodies produced by the mucins do react with the blood serum of the same species, still there are very marked quantitative differences in favor of the homologous mucin. In so far as the antibodies produced by one mucin react with other mucins from a different species as well as from the same species, support is given to the theory that specificity depends on the chemical nature of the antigenic protein rather than its biological origin."

Some new distomes from the intestinal tract of domestic animals and of pelicans for which fish serve as the source of infection, J. CTUREA (*Ztschr. Infektionskrank. u. Hyg. Haustiere*, 16 (1915), No. 6, pp. 445-458, pl. 1, figs. 3).—Three species of the new genus *Loossia* are described as new to science, namely, *L. romanica* from the dog, *L. parva* from the cat, and *L. dobrogiensis* from the pelican (*Pelecanus onocrotalus*). Feeding experiments show *L. romanica* to occur in *Esox lucius* and different fresh water fish of the subfamily Cyprininae, with the exception of *Tinca tinca*, and *L. parva* was once found in a cat after it had been fed on *E. lucius*.

The discovery of the anthrax bacillus, O. MALM (*Ztschr. Infektionskrank. u. Hyg. Haustiere*, 15 (1914), No. 3-4, pp. 195-208).—This is a historical review.

Remarks on the work of W. Pfeiler and G. Weber on the action of mallein on sound horses and the significance of the conglutination reaction for the diagnosis of glanders, J. SCHNÜRER (*Ztschr. Infektionskrank. u. Hyg. Haustiere*, 16 (1915), No. 4, pp. 305-308).—It is stated that the conditions under which Pfeiler and Weber conducted the experiments (E. S. R., 33, p. 479) are not those which obtain in practice, consequently the data can not be directly applied to practical conditions.

A reply to the remarks of Prof. J. Schnürer on the work of W. Pfeiler and G. Weber about the action of mallein with sound horses and the significance of the conglutination reaction for the diagnosis of glanders, W. PFEILER (*Ztschr. Infektionskrank. u. Hyg. Haustiere*, 16 (1915), No. 5, pp. 383, 384).—A discussion of the objects of the work previously reported (E. S. R., 33, p. 479).

The serological diagnosis of glanders in asses, hinnies, mules, and horses with the so-called nonspecific inhibition of complement fixation deviation, W. PFEILER and G. WEBER (*Ztschr. Infektionskrankh. u. Hyg. Haustiere*, 16 (1915), No. 5, pp. 311-323).—The object of this investigation was to determine whether it is possible by a modified complement fixation or another serological method to distinguish between specific and nonspecific antibodies in the sera of animals. See also notes by Schütz and Waldemann (*E. S. R.*, 33, p. 479).

It is concluded that this can be accomplished with the conglutination reaction (*E. S. R.*, 33, p. 479). In the investigation 6,500 sera were examined, among which there were 5 which did not give a specific deviation of complement. The agglutination values of these animals were in no case more than 500, but they could be regarded as suspects, whereas with the conglutination method only 1 of the 5 horses could be so regarded. This animal, on autopsy, was found glandered.

With the sera of 14 asses it was not possible to say whether glanders was present from either the complement fixation or agglutination test, but in one case it was noted with the conglutination test.

Necrobacillosis, A. T. KINSLEY (*Amer. Jour. Vet. Med.*, 10 (1915), No. 9, pp. 609, 610, 655, 656).—It is pointed out that necrobacillosis is a name given to a group of pathologic conditions caused by *Bacillus necrophorus* and characterized by inflammation and necrosis. This includes lip-and-leg ulceration and foot rot in sheep; stomatitis, enteritis, pneumonitis, hepatitis, splenitis, and dermatitis in swine; necrotic dermatitis in the horse; stomatitis in calves; ano-vulvitis in cattle, etc. An outbreak of ano-vulvitis in a feed lot of 115 head of heifers in Missouri in March, 1915, is reported upon.

The effect of quinin on rabies, C. KRUMWIEDE, JR., and ALICE G. MANN (*Jour. Infect. Diseases*, 16 (1915), No. 1, pp. 24, 25).—"Of four dogs treated with quinin, one showed a prolonged period of incubation and another showed a remission in the course of the disease, in either case, however, not beyond variations in the natural course of the disease. The fact that these variations occurred in the two of four dogs receiving the largest amounts of quinin is probably only a coincidence. No influence was observed on the period of incubation in rabbits."

The bovine hemoglobinuria of Chile, a disease due to spirochetiform parasites, J. BLIER (*Compt. Rend. Acad. Sci. [Paris]*, 159 (1914), No. 24, pp. 815-817).—A brief report upon a disease of cattle occurring in the region of Santiago, Chile, and known as "Meada de Sangre," which has often been confused with anthrax. The death of the affected animal nearly always takes place within 48 hours.

Agglutination studies of milk from cows affected with contagious abortion, L. H. COOLEIDGE (*Abstr. in Science, n. ser.*, 42 (1915), No. 1080, p. 352).—The author's investigations were carried on with milk from a herd having a record of frequent abortion and in which a high percentage of the animals had repeatedly given positive complement fixation and agglutination tests. The milk of 18 out of 61 cows, each quarter of which had been examined at intervals during a period of six months, gave a positive agglutination test with *Bacillus abortus* in one or more quarters at some time or during this period.

"The power of the milk of one quarter to agglutinate the abortion bacterium has been observed to spread to another quarter and finally to all four. It has also been observed to gradually die out. Milk drawn at about the middle of the milking has the strongest agglutinating reaction."

In an attempt to demonstrate the presence of *B. abortus* in milk that agglutinates the organism, the milk of 14 of 18 quarters produced lesions in guinea pigs typical of the pure culture of this organism. "In the seven cows whose

milk has gradually acquired the power of agglutinating the abortion bacterium during this experiment one or both of the rear quarters have been the first to show agglutination. This suggests contamination of the rear quarters by genital discharges."

Warble flies, S. HADWEN (*Canada Dept. Agr., Health Anim. Branch Bul. 16 (1912), pp. 20, figs. 15*).—The first part of this bulletin, relating to the economic aspect of warble flies, is based upon a questionnaire in which 36 replies have been abstracted and tabulated. This is followed by a brief account of the biology of *Hypoderma bovis* (pp. 7–20), a report on the occurrence of which in Canada has been previously noted (E. S. R., 29, p. 357).

It is concluded that the annual loss to hides through warbles in Canada amounts to between 25 and 30 per cent. The egg is laid close to the skin at the base of the hair on the legs and is cemented on by the ovipositor. The first larvæ, which were found in the esophagus on August 15, were under 5 mm. in length and were provided with minute spines on all segments. The author recommends that cattle be housed during the heat of the day, and that the grubs be squeezed out early in the season.

A list of 21 references to the subject is included.

A disease simulating beri-beri in pigs fed on rice meal, S. HADWEN (*Canada Expt. Farms Rpts. 1914, pp. 473–475*).—The author reports upon a noncontagious disease in pigs resembling beri-beri in man which developed during the course of feeding experiments with rice meal. It is pointed out that there was a variation in the toxic properties in different shipments of rice meal. The author is inclined to the opinion that the disease was caused by a toxin, since the pigs improved as soon as the meal was taken from the diet.

What is hog cholera? K. SCHERN and C. STANGE (*Ztschr. Infektionskrank. u. Hyg. Haustiere, 16 (1915), No. 4, p. 309*).—A polemic. In this connection, see work previously noted by Hutyra and Joest (E. S. R., 33, p. 285).

Two new cestode parasites of domestic fowl, K. J. SKRJBIN (*Ztschr. Infektionskrank. u. Hyg. Haustiere, 15 (1914), No. 3–4, pp. 249–260, figs. 9*).—A new tapeworm parasite from the hen in Brazil is described as *Davainca vigintivasus*, the eighth of the genus recorded from this host, and one from the duck (*Anus boschas domestica*) in Italy as *D. microcotyle*, the second species of this genus recorded from the duck. Lists are also given of the tapeworms recorded up to the present time from the hen, turkey, pigeon, duck, goose, and swan.

RURAL ENGINEERING.

Computing run-off from rainfall and other physical data, A. F. MEYER (*Proc. Amer. Soc. Civ. Engin., 41 (1915), No. 3, pp. 549–648, figs. 36*).—This paper points out the necessity of basing conclusions with respect to run-off or stream flow on extended physical data.

On the basis that run-off consists of the residual rainfall after all losses have been deducted, methods of computing these losses are treated in detail, taking up in their order losses due to evaporation from water surfaces, snow and ice, evaporation from land areas, and transpiration of plants. In this connection a number of curves and other data based largely on observations are given. A summary statement of the author's method of computing run-off is made and the method applied to 15 widely different watersheds. The main features of this method are as follows:

"I. Collection of physical data.—(A) Rainfall and temperature data for stations on and near the given watersheds from which monthly rainfall and temperature for the watershed are estimated. Rates of excessive rainfall at different reasons of the year as indicated by Weather Bureau observations at

the nearest regular station. In case rainfall and temperature data are meager, charts showing isotherms and isohyets for the portion of the State in which the watershed is situated are of assistance. (B) Data relating to wind velocity, relative humidity, and any other prominent weather characteristics. (C) Data relating to topography, vegetal cover, soil, and subsoil as affecting evaporation. (D) Data relating to character and density of vegetation and length of growing season with reference to temperature and hours of sunshine. (E) Data relating to area of open-water surfaces, swamps, and marshes.

"II. Determination of losses.—(A) Evaporation from water area: (1) Monthly evaporation corresponding to given temperature and season, and multiplied by percentage of water surface, based on data under I-E, and coefficient based on data under I-B. (B) Evaporation from land area: (1) Determination of coefficient for given watershed, based principally on physical data under I-C and I-B. (2) Determination of evaporation, in inches depth per month, corresponding to given monthly temperature and rainfall for given season of year, from curve of evaporation from land areas, and multiplication of the same by percentage of land area and coefficient determined under II-B-1. (C) Transpiration from land area: (1) Determination of normal seasonal transpiration, based on physical data under I-D. (2) Determination of transpiration coefficient by finding ratio between seasonal transpiration determined from base curve of transpiration for the normal monthly temperatures for the given watershed, and the normal seasonal transpiration determined under II-C-1. (3) Determination of monthly transpiration by applying transpiration coefficient to monthly values taken off transpiration curve for given monthly temperatures, and modification of these monthly values on basis of rainfall, percolation, and storage.

"III. Determination of total loss by summation of monthly losses from land and water areas, the deduction of these monthly losses from the monthly precipitation, and summation of these monthly residuals to give the annual yield of the given watershed, with or without correction of this annual total for fall surface run-off or changes in ground and surface storage.

"IV. Where the annual yield and its distribution throughout the year are both desired, additional curves . . . and computations for the same watershed must be made. When the more detailed computations, as here indicated, are carried out, it is possible to make more accurate estimates of transpiration during months of deficient rainfall, because more accurate values of soil and subsoil storage are available."

Other special applications of the author's method are discussed in detail with data from observations.

Snow survey provides basis for close forecast of watershed's yield, J. E. CHURCH, JR. (*Engin. Rec.*, 71 (1915), No. 16, pp. 494, 495, figs. 3).—Rapid and economical methods of measuring large areas of snow at high altitudes are described which have proved useful at Lake Tahoe, Nev.

"The general method pursued was to determine the water content of the snow on typical slopes and under characteristic forest covers, making each topographic unit as large as possible. Measurements were made in sufficient sections of the basin to determine the local difference in snowfall, and enough courses at high levels were measured to determine the relation of the snowfall on the higher slopes of the watershed to that on the floor of the basin. The courses did not always follow contour lines but were frequently diagonal and sometimes vertical to them, being so laid as to determine the water content of the slope in question."

It is stated that the method of snow surveying is a practical substitute for the expensive method of contour line surveying.

A method of correcting river discharge for a changing stage, B. E. JONES (*U. S. Geol. Survey, Water-Supply Paper 375-E (1915), pp. 117-130, figs. 6*).—It is pointed out in this paper that “when a river is rising fast it has a greater velocity and a greater discharge than it has at the same height when its stage is constant. Likewise, when it is falling fast it has a lesser velocity and a lesser discharge. For this reason the relation of gage height to discharge which applies under conditions of constant stage will not apply during times of changing stage, . . . especially . . . if the slope of the river is small. . . . The increased discharge at a given gage height during a rising stage is due to the increase in slope, and the opposite is true for a falling stage. Therefore, the smaller the natural slope of the stream the greater is the proportional change in slope for any given rate of change in the stage.”

For the purpose of correcting the discharge for a changing stage so that proper relations between gage height and discharge may be established for certain conditions the following formula, based on Chezy's formula for flow of water in open channels, is mathematically derived:

$$\frac{Q_1}{Q_2} = \frac{\sqrt{S_1}}{\sqrt{S_1 + \frac{K}{V}}} = \frac{\sqrt{S_1}}{\sqrt{S_1 + \frac{NK}{V}}}$$

In this formula Q_1 =the discharge at constant stage, Q_2 =the discharge for changing stage, S_1 =slope at constant stage, K =rate of change of stage per second, V =the mean velocity of the measurement made during the changing stage, and N =the coefficient “for obtaining mean velocity from surface velocity.” It is assumed that the flood travels very nearly at the rate of the surface velocity. “Therefore, to obtain the velocity of the flood, that is, the surface velocity—the mean velocity of the measurement should be divided by 0.9 for large streams and by 0.85 for smaller ones. . . . In order to compute the actual discharge from gage heights observed during a changing stage it is necessary to have the cross section at the gage and a slope curve in addition to the discharge curve and mean velocity curve for constant stage. Then the discharge may be assumed to be equal to that at the same gage height at a constant stage, and the approximate mean velocity, surface velocity, and corrected discharge may be obtained. The corrected discharge may then be used in obtaining a new surface velocity and a second correction obtained. This can be repeated until the error is negligible, but once will usually be sufficient.”

Data from actual applications of this method are also given.

Conditions requiring the use of automatic gages in obtaining records of stream flow, C. H. PIERCE (*U. S. Geol. Survey, Water-Supply Paper 375-F (1915), pp. 131-139, figs. 6*).—The conditions which require the use of automatic gages are summarized as follows: (1) Regulation of the stream by power developments, (2) operation of canals and ditches delivering water for irrigation, (3) fluctuations due to variation in run-off under natural conditions (*a*) caused by rain and (*b*) caused by melting ice and snow, (4) inaccessibility of gaging station or lack of reliable observer, (5) continuous record needed for legal purposes, and (6) human fallibility of most gage observers. These conditions are briefly discussed.

Small automobile opens up new opportunities in Government stream gaging work, E. A. PORTER (*Engin. Rec., 71 (1915), No. 16, pp. 490, 491, figs. 3*).—Data collected by the U. S. Geological Survey indicate that in a number of the Western States the small automobile is more efficient in stream measurement work than a team.

Ground water in Big Smoky Valley, Nevada, O. E. MEINZER. (*U. S. Geol. Survey, Water-Supply Paper 375-D (1915), pp. 85-116, pls. 2, figs. 2*).—This paper describes the geography and physiography and reports an investigation of the underground water resources, with reference to their development for irrigation, of an area of 3,250 square miles, extending from about the geographic center of Nevada to a point less than 20 miles from the California line.

“The drainage basin of Big Smoky Valley is divided by a low, gentle, alluvial swell west of Manhattan into a north basin, which contains the upper valley, and a south basin, which contains the lower valley. Each of these basins at present contains an alkali flat. Ione Valley, which lies west of Big Smoky Valley proper and has a drainage basin of about 500 square miles, discharges into the lower valley from the northwest and hence forms a part of the south basin.” The climate is arid and exhibits the characteristic features of aridity.

It is concluded from the investigation that “several tens of thousands of acre-feet of ground water is probably annually available for irrigation in Big Smoky Valley. Most of this supply is in the upper valley, but a part is in the vicinity of Millers in the lower valley. The water is in general of satisfactory quality for irrigation. Nearly all of the poor water is in the southwestern part of the lower valley, where there is practically no prospect for irrigation. A small part of the ground-water supply can be recovered by means of flowing wells, but full use of the supply can be obtained only by pumping. Throughout the extensive areas in which the depth to the water table does not exceed 10 ft. the soil contains injurious amounts of alkali. In the areas in which the depth to the water table ranges between 10 and 50 ft. there is enough good soil to utilize all the ground-water supply. These areas, however, also contain considerable gravelly, sandy, and alkaline soil. There are some prospects of obtaining flowing wells wherever the water table is near the surface, but the prospects are best on the west side of the upper valley. The flowing-well areas will be found to lie chiefly within the areas of alkali soil, but they may extend into adjacent areas of good soil.

“Full development of the ground-water supply for irrigation will not be economically practicable until cheaper power or more valuable crops can be introduced than are now in sight. Developments believed to be practicable at present are (1) the sinking of flowing wells of moderate depths in the restricted areas where fairly copious flows can be obtained and the soil is not irreclaimably alkaline, and (2) the sinking of nonflowing wells and the installation of pumping plants for raising high-priced crops and for raising ordinary crops in localities where the conditions are exceptionally favorable or where the well water can be used to supplement surface-water supplies. The raising of high-priced crops is practicable to only a small extent. Vegetables and small fruits could, it is believed, be profitably raised in the vicinity of Millers to supply Tonopah, Goldfield, and other local markets.

“The principal favorable conditions that are necessary in order to make pumping profitable for raising ordinary crops, such as alfalfa, are soil that is not injuriously alkaline, sandy, or gravelly; small depths to the water table (not much more than 10 ft.); and water-bearing beds at moderate depths that will yield freely.

“Existing conditions do not warrant the influx of a large number of settlers nor of any without means to sink wells and make other necessary improvements.”

A contribution to the study of the actions of various waters upon lead, H. HEAP (*Jour. Soc. Chem. Indus., 32 (1913), Nos. 15, pp. 771-775; 16, pp. 811-815; 17, pp. 847-856*).—A historical review of work bearing on the subject is given, and experiments are reported to determine the effect of various waters and solutions on more or less impure lead pipes and on pure lead.

It was found that pure distilled water, free from dissolved gases, exerts but a very slight action upon lead. The action is greatly modified when certain gases, especially hydrogen, carbon dioxide, oxygen, and air are dissolved in the water. The phosphates of calcium and sodium when dissolved in water seemed to prevent entirely the dissolving of lead. The carbonates and bicarbonates of the alkaline metals and earths ranked next in preventive action.

Along with a number of other results, it was found that "the purer natural waters, such as rain water and the waters from streams (before they have had the opportunity of dissolving much mineral or organic matter or received material amounts of spring waters), exert actions which are comparable with the action of ordinary distilled water. Rain waters containing large quantities of acids react like distilled water containing acids. Moorland waters are generally very free from dissolved mineral matter, but contain varying amounts of organic matter and are usually very soft. [They] may have alkaline, neutral, or acid reactions; they generally attack lead rather vigorously, but seldom more actively than distilled water. The waters gathered from peaty moorlands exhibit at certain seasons an increased acidity, but this can not account for the amount of lead with which they become contaminated. . . . Distilled water and rain water showed diminished actions upon lead after contact with peat, but the reverse was the case with a soft upland lake water and with a hard spring water. . . . Lake waters, which are naturally very pure and contain only small amounts of saline matter, exert a much weaker action than either rain water or distilled water. Their action, though generally of a low degree, is liable to variation during different seasons."

The water supply of farm homesteads, F. T. SHUTT (*Canada Expt. Farms Rpts. 1914, pp. 90, 129-135*).—Analyses of 168 samples of farm water supplies are reported, which show that 62 were pure, 44 were of doubtful quality and probably dangerous, and 25 were seriously contaminated. Thirty-four samples were too saline for potable use.

For the isolated farmhouse the bored or drilled well, tapping a deep-seated source of water, is strongly advocated. It is also suggested "that the area around the well, say for a radius of at least 50 yds., be kept free from manure and all filth. It may preferably be kept in sod. Another precaution of considerable value toward the protection of the well water from organic filth is to line the well to a depth of say 10 to 12 ft. and to a thickness of say 6 in. with concrete or puddled clay. This lining should project some 6 to 12 in. above the mouth of the well."

The application of water to citrus orchards and the maintenance of the proper moisture content of the soil, W. M. MERTZ (*Mo. Bul. Com. Hort. Cal., 4 (1915), No. 3, pp. 140-145*).—In this paper the points which are considered of prime importance in the irrigation of citrus orchards are summarized as follows:

"Lay off the land so that the furrows will not be . . . longer than 400 or 500 ft. or with a fall of more than 6 in. to the 100 ft. If the land is comparatively level use pipe line and standpipes as a distributing system, otherwise use the cement flume. Furrow . . . at least 6 in. deep. When starting the water run it as rapidly from the flume to the lower end of the furrow as the grade will permit without washing, then cut the head down to prevent waste from the end. Run the water long enough to have the soil soaked to the 4-ft. level at the lower end of the furrow, then turn it off. Harrow to fill the furrows as soon after irrigation as the soil will work without puddling the soil on which the team walks. As soon as the deeper soil is dry enough to work mellow; cultivate deeply. Duplicate every two weeks until the next irrigation."

Irrigation practice in the Sacramento Valley, W. S. GUILFORD (*Mo. Bul. Com. Hort. Cal.*, 4 (1915), No. 3, pp. 123-128).—In this article the author discusses briefly the choice of the land, the object of the irrigation, the preparation of the land, and the water delivery system as points which he considers have been the cause of success or failure on the part of irrigators in the valley.

Report of the proceedings of the eighth annual convention of the Western Canada Irrigation Association, 1914 (*Rpt. Proc. Ann. Conv. West. Canada Irrig. Assoc.*, 8 (1914), pp. 216, figs. 36).—The text of the proceedings is given.

Biennial report of the state geologist, 1913-14, J. H. PRATT (*N. C. Geol. and Econ. Survey, Bien. Rpt. State Geol.*, 1913-14, pp. 176, pls. 4).—This report includes among other things sections dealing with road-building materials, highways, drainage, and soil maps.

The St. John Levee and Drainage District of Missouri, R. M. STROHL (*Proc. Amer. Soc. Civ. Engin.*, 41 (1915), No. 3, pp. 523-547, pls. 5, figs. 2).—This paper treats of some of the drainage problems of southeastern Missouri and gives in detail the data necessary to be considered in designing a system for the complete and economical reclamation of large tracts of overflow land. Levees, floodways, drainage ditches, floodgates, storage basins, and siphons are considered and discussed in detail as they are found necessary. The assessment of benefits as provided for under the Missouri laws is also outlined and applied to the case and an effort has been made to show a just and equitable distribution of the cost of the proposed work.

The experiment-farm drainage system, F. B. HEADLEY (*U. S. Dept. Agr., Bur. Plant Indus., Work Truckee-Carson Expt. Farm, 1914*, pp. 10-12, fig. 1).—The results of experimental drainage work on the project during 1914 are reported (*E. S. R.*, 31, p. 889), certain data being summarized as follows:

Quantity and salt content of water pumped from the tile-drainage system on the Truckee-Carson Experiment Farm in 1914.

Month.	Electricity used.	Water pumped.		Salt content.	
				Average.	Total.
	<i>Kilo-watts.</i>	<i>Cubic feet.</i>	<i>Pounds.</i>	<i>Per cent.</i>	<i>Pounds.</i>
January.....	29	35,960	2,247,500	0.249	5,598
February.....	38	47,120	2,945,000	.278	8,187
March.....	76	94,240	5,890,000	.322	18,966
April.....	92	114,080	7,130,000	.305	21,747
May.....	95	117,700	7,356,250	.313	23,025
June.....	74	91,700	5,728,750	.276	15,811
July.....	148	183,520	11,470,000	.290	33,263
August.....	146	181,040	11,315,000	.351	39,716
September.....	63	78,120	4,882,500	.360	17,577

November.....	72	89,280	5,580,000	.304	16,963
December.....	40	49,600	3,099,700	.447	13,856
Total.....	921	1,141,940	71,365,800	.3216	228,253

Methods and cost of levee enlargement with a tower dragline excavator (*Engin. and Contract.*, 43 (1915), No. 19, pp. 417-420, figs. 11).—This article describes the organization and methods employed in operating a newly developed type of excavator on a 240,000-cu. yd. contract for levee enlargement on the Mississippi River. The excavator used consists of two traveling towers between which a bucket controlled by a slackline cable is dragged back and forth, the propelling power being supplied by a dragline and operated from the main tower.

Wearing tests for sand and gravel, F. L. ROMAN (*Good Roads, n. ser., 9 (1915), No. 18, pp. 183, 187*).—This article describes two tests of the wearing qualities of aggregates which have been used in the laboratory of the Illinois highway department.

The wearing test for sand consists essentially of submitting a given weight of sand to the wearing effect of an ordinary Deval abrasion machine, the cast-iron cylinders of which contain a certain weight of small steel shots. After 1,000 revolutions at 30 to 33 per minute the material passing a 100-mesh sieve is considered as the wear. Data from a number of such tests show practically no wear in the case of Ottawa sand and very little wear in the case of sands composed mainly of quartz. The mixed sands show average wearing qualities while the limestone sands give the poorest wear.

The wearing test for gravel is also performed in the Deval abrasion machine. No shots are used, the wear being caused by the grinding of the stones against each other and the sides of the cast-iron cylinders.

Effect of fineness of sand and of clay and loam on the strength of mortar, F. L. ROMAN (*Engin. and Contract., 43 (1915), No. 18, pp. 403-406, figs. 10*).—Tests made by the Illinois highway department on the effect of various percentages of fine sand below 50-mesh on the strength of mortar, with particular reference to highway structures, brought out the following conclusions:

“In a well-graded sand the presence of fine material passing the No. 50 sieve causes a decrease in the strength of its 1:3 mortar, the strength of the 1:3 mortar obtained from the portion of the same sand retained on the No. 50 sieve being taken as the basis of comparison. In a badly graded sand the presence of a small proportion of clean sand passing the No. 50 sieve might probably, under certain conditions, cause a slight increase in the strength of the mortar, but the presence of a large proportion of the material passing a 50-mesh sieve will cause a decrease in strength. . . .

“Small amounts of clay in sand seem to cause a small increase in the strength of the mortar. The tensile strength curve of 1:3 mortar briquettes in which the sand contains increasing percentages of clay rises at first with small quantities of clay. With larger quantities of clay, however, the strength begins to drop. . . .

“Organic loam in sand, even in very small quantities, will cause a decrease in the strength of the mortar. In the tests $1\frac{1}{2}$ per cent of organic matter in sand caused a decrease in the tensile strength of 1:3 mortar of 15 to 20 per cent. Often 1 per cent and sometimes 2 or 3 per cent of organic matter in sand can not be detected in the general appearance of the sand, and whenever the sand appears dark and loamy it is a sure sign that it should be tested before using in concrete work.”

Concrete road with a single crack in $4\frac{1}{4}$ miles, the result of careful construction (*Engin. Rec., 71 (1915), No. 16, pp. 480-482, figs. 11*).—A description of the construction of $4\frac{1}{4}$ miles of concrete road which has stood for one year with only one crack is given. Features in the construction were thorough rolling of the subgrade, adequate provision for drainage, minimum time for mixing each batch of concrete, careful grading of sand, accurate measurement of concrete materials in boxes, and use of wire-mesh reinforcement.

The concrete road is single course, 18 ft. wide, 8 in. thick at the center, and 6 in. thick at the sides. The foundation is an old macadam road and the maximum grade 5.8 per cent. The contract cost was \$15,914 per mile.

Brick highways in King County, Washington, F. W. ALLEN (*Municipal Jour., 37 (1914), No. 23, pp. 795-799, figs. 8*).—This article gives data regarding the cost, methods of construction, and methods and results of tests of materials for brick-surfaced country roads to withstand a heavy rural traffic.

There have been constructed 21.74 miles, aggregating 246,150 sq. yds., of brick roads at a cost per yard of \$2.37, or a cost per mile of \$27,297. A 5-in. concrete base of 1:3:6 was used and a concrete curb was poured at the same time as the base. The brick surface was laid on a 1½-in. sand cushion and rolled by a 2½ to 3½ ton roller. Expansion joints were placed along the curb line and every 100 ft. transversely.

In tests of brick for the modulus of rupture, in which the brick were broken between supports 6 and 7 in. apart, the average modulus in one set of tests was 2,512 lbs. per square inch. Tests were also made of sections of brick pavement, constructed as beams, 12 in. wide of 42-in. span and loaded at the center, in order to study the efficiency of differently mixed cement joints. With a 1:1 grout the plane of failure cut across one brick and for the rest of the way was through the bond. In one instance a lug was sheared off. With the 1:1½ grout the failure in one case was across two bricks and the rest of the way through the bond and in the second case was through the bond all the way. With the 1:2 grout the failure was entirely through the bond in each instance. In no instance was the failure through the grout.

The author is of the opinion that these results indicate the advantage of using a 1:1 grout rather than a leaner mixture or paving pitches, and concludes that the brick surface is dependable to distribute the load over a larger area on the foundation.

Methods and cost of constructing a mountain road system in Wise County, Virginia. W. F. Cocke (*Engin. and Contract.*, 43 (1915), No. 15, pp. 341-344, figs. 6).—This article gives a complete history of a system of roads in a county in Virginia, describes methods and cost of excavation, and gives a table of solid cuttings on sidehill excavation.

Proceedings of the first annual good roads week at Cornell University (*Cornell Civ. Engin.*, 23 (1915), No. 6-7, pp. 217-478, pl. 1, figs. 19).—These proceedings include the following special articles:

Survey and Plans for Road Work, by M. W. Nelson; Road Drainage, by M. J. Adams; Town Roads, by W. F. Wilson; Road Materials Available in New York State and Their Adaptability for Different Types of Construction, by H. S. Mattimore; Highway Culverts and Bridges, by O. L. Grover; Public Borrowing for Road Building, by A. A. Young; Gravel Roads, Road Economics, and Sand-Clay Roads, by L. I. Hewes; Surface Treatments and Bituminous Construction, by H. E. Smith; The Mining and Refining of Lake Asphalts and the Physical and Chemical Characteristics of Asphalts for Paving Purposes, by J. S. Miller; Asphalt Block Pavement, by G. P. Hemstreet; Cost and Economy of Cement Concrete Pavements and Standard Recommended Practices for Construction of Concrete Roads, by H. E. Hiltz; Organization of a Highway Department, by G. A. Ricker; Masonry and Foundations, by H. S. Jacoby; Inspection of Highway Bridges, by C. L. Crandall; Manufacture and Inspection of Paving Brick and Construction of Brick Pavements, by W. P. Blair; Proper Construction of Brick Pavements, by W. C. Perkins; Cost Keeping and Management, by F. A. Barnes; and Prospecting for Road Material, by H. Ries.

Wheel tire width and weight of load for conveyances with animal draft. J. DUHM (*Ztschr. Transportw. u. Strassenbau*, 32 (1915), No. 1, pp. 16-19).—This article discusses the conditions affecting the relations between the tire width, the load on the wagon, and the condition of the road surface, with particular reference to conditions and practice in districts of Austria.

In the Tyrol the following relations between tire width and load are proposed:

Tire width for different loads on different wagons.

Road surface condition.	Kind of wagon.	Gross weight of load.	Tire width.
			<i>Inches.</i>
Dry.....	4-wheeled.....	Less than 4,400 pounds.....	2.3
Do.....	do.....	Less than 7,700 pounds.....	3.1
Do.....	do.....	Less than 11,000 pounds.....	3.9
Do.....	do.....	Less than 14,300 pounds.....	4.7
Do.....	do.....	Less than 17,600 pounds.....	5.5
Wet and muddy.....	do.....	Less than 3,080 pounds.....	2.3
Do.....	do.....	Less than 5,280 pounds.....	3.1
Do.....	do.....	Less than 7,480 pounds.....	3.9
Do.....	do.....	Less than 9,680 pounds.....	4.7
Do.....	do.....	Less than 11,880 pounds.....	5.5
Dry.....	2-wheeled.....	Less than 3,300 pounds.....	2.3
Do.....	do.....	Less than 6,600 pounds.....	3.1
Do.....	do.....	Less than 9,900 pounds.....	3.9
Do.....	do.....	Less than 13,200 pounds.....	4.7
Wet and muddy.....	do.....	Less than 2,200 pounds.....	2.3
Do.....	do.....	Less than 4,400 pounds.....	3.1
Do.....	do.....	Less than 6,600 pounds.....	3.9
Do.....	do.....	Less than 8,800 pounds.....	4.7

It is proposed to limit the rounding of the tire on both sides to 0.197 in., and to use at least a 2.3-in. tire on light spring vehicles for personal transport the total weight of which will not exceed 6,600 lbs. For 4-wheeled wagons the minimum wheel diameter is given at 31.5 in., and for 2-wheeled 51 in. Each wagon owner is to be required to label his wagon, showing his name and location, the tire width of the wheels, and the corresponding maximum load.

A good commercial dairy barn, J. BEGIN (*Canada Expt. Farms Rpt. 1914, pp. 376-379, pls. 4*).—Plans and specifications for a modern commercial dairy barn erected at the substation at Ste. Anne De La Pocatière, Quebec, are given. This is considered to be an example of capacity, strength, lightness of structure, convenience, light, and ventilation in a dairy barn.

Cow barns, W. W. HUBBARD (*Canada Expt. Farms Rpts. 1914, pp. 366-368, pls. 2*).—Plans and statements regarding the general points of construction of the new cow barns recently erected at the substation at Fredericton, New Brunswick, are given.

Horse barn, W. W. HUBBARD (*Canada Expt. Farms Rpts. 1914, pp. 408, 409, pl. 1*).—Plans and statements regarding the general points of construction of a new horse barn for 15 horses recently erected at the substation at Fredericton, New Brunswick, are given.

Horse barn, J. BEGIN (*Canada Expt. Farms Rpts. 1914, pp. 413, 414, pls. 2*).—Plans and brief specifications of a new horse barn for 15 horses recently erected at the substation at Ste. Anne De La Pocatière, Quebec, are given.

Horse barn, W. C. MCKILLICAN (*Canada Expt. Farms Rpts. 1914, p. 415, pls. 5*).—Plans and photographic views, with a brief description, are given of a new horse barn recently constructed at the substation at Brandon, Manitoba.

Piggery, W. C. MCKILLICAN (*Canada Expt. Farms Rpts. 1914, pp. 454-456, pls. 3*).—Plans and brief specifications of a piggery recently erected at the substation at Brandon, Manitoba, are given.

Poultry houses and appliances for allotment holders, cottagers, and others (*Bd. Agr. and Fisheries [London], Spec. Leaflet 11 (1915), pp. 8, figs. 4*).—This pamphlet points out briefly the essential features of poultry houses from the English viewpoint, and gives specifications and bills of material for apex portable and stationary poultry houses, scratching sheds, and coops.

A cheap root cellar, W. H. FAIRFIELD (*Canada Expt. Farms Rpts. 1914, p. 940, pls. 2*).—It has been found that a convenient way to build a root cellar at small expense is to make an excavation about 6 ft. deep and cover it with

7 or 8 ft. split cedar fence posts laid 5 to 7 in. apart. Over these is put a foot or more of straw and then 2 ft. of soil. It is stated that little trouble is ever experienced with the sides giving way, provided rain water is not allowed to substation at Brandon, Manitoba, are given.

Cotton warehouse construction, R. L. NIXON (*U. S. Dept. Agr. Bul. 277 (1915), pp. 38, figs. 13*).—The purpose of this bulletin is to outline in a general way some of the essential features of a warehouse for the storage of cotton. A general discussion of the importance of storage houses and the principles of storage, particularly as applied to cotton, is followed by a statement of the functions of a warehouse, which are as follows:

(1) It offers temporary storage facilities when the owner is not in a position to store it himself. (2) It should furnish the owner of the stored product a negotiable receipt. (3) It provides a reservoir for surplus during years of over-production or when market conditions are very unsatisfactory.

The general features of construction of types of standard warehouses, including the closed detached cotton warehouse with compartments limited to 600 bales capacity, the detached cotton warehouse of frame construction, the closed cotton warehouse limited to 1,000 bales capacity, the cotton warehouse with open court, the open court warehouse of fire resistive construction, the single or compartment warehouse of fire resistive construction, open shed compresses with platforms and yards attached, and emergency sheds, are described and illustrated. Miscellaneous fire insurance schedules, insurance standards for warehouse construction, and general considerations relative to cotton storage and fire insurance are also given.

It is considered very important to have a cotton warehouse conveniently located on a sidetrack and to provide ample platform space.

A system of automatic sprinklers is considered to be a desirable installation for a cotton warehouse. Special warning is given against the placing of a wire fence around yards or sheds inasmuch as it will interfere with the handling of the cotton during a fire and consequently increase insurance rates.

The importance of having warehouses conform to the standards of the underwriters' association is urged. It is finally stated that the diagrams in this bulletin should not be treated as plans for building, and the importance of employing a competent architect to draw up specifications for any warehouse is emphasized.

Farm sanitation with special reference to water supply and sewage disposal, P. HANSEN (*Trans. Amer. Soc. Agr. Engin., 7 (1913), pp. 62-96, figs. 15*).—The substance of this article has been noted from another source (*E. S. R., 32, p. 87*).

Sanitary apparatus for the disposal of excreta and sewage from private residences and isolated houses, F. C. SNOW (*Mont. Bd. Health Spec. Bul. 2, pp. 31, figs. 17*).—This pamphlet deals with the disposal of farm and residential sewage.

With reference to conditions where water under pressure is not available the so-called dry system, wet system, sanitary pail, and several modifications of the L. R. S. sanitary privy (*E. S. R., 25, p. 891*) are described. With reference to conditions where water under pressure is available, cesspools and the well-known septic tank and filtration system are described. Cost data to suit Montana conditions are given for the different types and arrangements of equipment.

The purification of dairy wastes, G. B. KERSHAW (*Surveyor, 46 (1914), No. 1197, pp. 736, 737*).—The author states that the uniform attainment of standards for dairy sewage having limiting figures of 3 to 4 parts per 100,000

of suspended matter and similar figures for dissolved oxygen taken up from water in five days at 80° F. is desirable.

He prefers the use of a precipitant as a preliminary treatment rather than a septic tank. The best filter is considered to be the deep percolating filter.

"Distribution should be good in order to obtain the best results. In many districts peat is obtainable, and may be used as a distributor for certain types of filter. It requires, however, frequent attention and renewal if satisfactory results are looked for. The used peat possesses good manurial properties.

"With regard to the treatment of dairy wastes upon land, it is desirable that there be some form of preliminary treatment before the liquid is treated on the land, in order to remove solids which would otherwise tend to choke the pores of the soil. . . . Concerning the rate of treatment of dairy wastes upon land, much will depend upon the quality of the soil and subsoil, but with land of medium quality from 3,000 to 4,000 gal. per acre per twenty-four hours of settled or strained liquid is probably a safe dose. Much, however, depends upon the nature of the intermittency of the irrigation. Grass land is especially benefited by the careful application of dairy wastes."

Report summarizing the work of the public commission for the testing of processes for the purification of sewage from sugar refineries from 1899 to 1913, C. GÜNTHER and A. HERZFELD (*Mitt. K. Landcsanst. Wasserhyg. Berlin-Dahlem, No. 18 (1914), pp. 1-32*).—It is concluded from the results of this work that there are numerous points in the process of purification of sewage from sugar refineries which need further systematic investigation. The work so far has shown that there is no single process which may be considered adaptable to all cases. Surface irrigation, while successful in many cases, is generally unsuccessful owing to the land area required. The combination of land irrigation and lime treatment processes is generally unsuccessful for the same reason and on account of the bad effect on the physical condition of the soil. Since no universal process is available it is considered necessary to base the selection of the process to be used entirely on local conditions.

The operation of sewage disposal plants, F. E. DANIELS (*New York: Municipal Journal, 1914, pp. [VIII]+136, figs. 40*).—This book presents a series of articles on the practical management and operation of sewage disposal plants, the main purpose being "to assist the plant attendant by pointing out to him many things he should do and some he should leave undone, in order that he may be able to keep his plant up to its highest state of efficiency at a minimum expenditure of cost and energy. Likewise it has been endeavored to show that poor designs are troublesome, costly, and inefficient."

The following chapters are included: Grit chambers and screens, tanks, filters, disinfection, chemical precipitation and electrolytic treatment, trade wastes, testing stations, making tests, and records of plant operation.

It is stated that a much larger area is required for the treatment of sewage by sewage farming than is required for the process of intermittent sand filtration. "Usually only about 10,000 gal. per acre per day can be successfully treated upon a broad irrigation area, while ten times that amount can be taken care of upon a good sand bed. Unless carefully managed, the process is likely to be objectionable if near built-up communities on account of odors, flies, and unsightliness. . . . In some localities good crops have been raised, notably in California, but take it all in all, sewage farming is not a paying operation. . . .

"A low or marshy area should never be selected to receive sewage, because under such conditions there is danger of a nuisance without a purification of the sewage. Light, sandy or loamy soils with free drainage are the most suitable, while stiff clay is almost worthless. . . . The attendant must know just

how much water each crop can stand, and to preserve the proper balance between the raising of crops and the disposal of the water often requires considerable skill and experience. Usually in wet weather, when the crops need the least added water, the sewage flow is the greatest, hence its disposal at such seasons is more difficult. . . .

"Corn and forage crops are raised and sometimes fruit and vegetables. . . . Berries, salad greens, celery, and low-growing fruits and vegetables, which are eaten raw, should not be raised. . . .

"Extended sewage areas often have a direct effect upon neighboring wells. Such wells should be frequently examined, and in the location of new works the wells in the vicinity should be considered."

Treat Illinois sewage with activated sludge (*Engin. Rec.*, 71 (1915), No. 14, pp. 421, 422, figs. 4).—Experiments on the treatment of sewage by the activated sludge principle showed a marked reduction in the time required for complete nitrification as compared with the time required when simple aeration was employed. With straight aeration this time varied from 15 to 33 days, while when the sludge was added complete nitrification was affected in only four days and the reduction in the amount of air used was from 4,830 to 1,270 cu. ft.

Analyses of the sludge showed that the dried material contained 6.3 per cent nitrogen, 1.44 per cent phosphorus, and 75 per cent volatile matter. It is considered valuable as a fertilizer. Pot culture experiments using the sludge and dried blood showed better growths for the sludge at the end of 18 days than for the dried blood and far better growth than on the unfertilized pot.

See also previous note by Ardern and Lockett (*E. S. R.*, 32, p. 387).

RURAL ECONOMICS.

Early economic conditions and the development of agriculture in Minnesota, E. V. ROBINSON (*Univ. Minn., Studies Soc. Sci.*, No. 3 (1915), pp. V+306, figs. 221).—This study outlines in great detail the agricultural development of Minnesota. After describing the physical features, climate, early travel, trade, and transportation, and the development of pioneer agriculture prior to 1860, the author traces the changes in agricultural conditions by ten-year periods from 1860 to the present time. The transition from the specialized wheat farming to diversified farming, with its accompanying causes and effects, is given.

The text is accompanied by a large number of maps and diagrams and statistical tables. The appendix contains an extensive bibliography.

Social and economic survey of a community in northeastern Minnesota, G. P. WARBER (*Univ. Minn. Current Problems No. 5* (1915), pp. VI+115, figs. 35).—This report is based upon a study of the town of Braham, Minn., and the surrounding territory. Among other things, the author concludes that "a good producers' association would help to get much larger returns, even if the marketing were left to the present competing jobbing concerns.

"The farmers of the community should discuss regularly in club meetings methods of improving farming and marketing conditions. There is plenty of local talent to conduct these meetings with programs of the proper kind."

He points out that the "county ditches" have done much to drain this country, and have accomplished the first thing necessary in the construction of good roads, but it is necessary to go slowly in improving the roads because the kind and amount of traffic the farmers have to do does not warrant inordinate expenses, such as is entailed in the construction of macadam and concrete roads.

"Owing to the gradual change wrought by newcomers of different nationalities, and the dissemination of socialistic doctrines with their usual agnostic

accompaniments, the church is losing control over the ethical and moral standards and aspirations of the community. The evident remedy is that ministers of the gospel should be men not only thoroughly imbued with Christian ideals, but should also have a practical appreciation of American standards and practices in business and social life."

Rural morality, P. L. VOGR (*Soc. Hyg.*, 1 (1915), No. 2, pp. 207-219).—The author in attempting to get a picture of the moral life of rural and village communities collected data in two counties in one of the middle Western States. The data relate to the number of cases of venereal disease treated during the past year, the evidence of forced marriages as shown by comparison of marriage dates with records of birth of the first child, extent of illegitimacy, records of juvenile courts, records of criminal cases in the county and before mayors and justices of the peace, and divorce records. The value and the limitations of each type of data are discussed and important factors influencing the morality of rural communities are pointed out.

Deficiencies in Italian agriculture (*Staz. Sper. Agr. Ital.*, 47 (1914), No. 4, pp. 241-281).—The author notes that Italy imports a large quantity of grain in various forms, which he believes should be produced within the country. He points out the causes for this situation, and outlines means that may be employed to counteract it, among which are agricultural schools, experiment stations, and the establishment of better systems of crop rotation.

Cooperation in Spanish agriculture (*Internat. Inst. Agr. [Rome]*, *Mo. Bul. Econ. and Soc. Intcl.*, 6 (1915), Nos. 3, pp. 10-27; 5, pp. 14-25).—This article describes legislation concerning cooperative societies, and the organizations for cooperative credit and for the purchase and sale of agricultural produce and supplies. A number of statistical tables are given showing the progress of the various types of organization.

Agricultural credit, EDNA D. BULLOCK (*New York: H. W. Wilson Co.*, 1915 pp. XIV+177).—This book is intended as a source of information on agricultural credit for students and others, and contains an extensive bibliography and a number of selected reprints.

Middlemen in English business, particularly between 1660 and 1760, R. B. WESTERFIELD (*Trans. Conn. Acad. Arts and Sci.*, 19 (1915), pp. 113-445, pls. 7).—This book describes the function of the middlemen in English trade between 1660 and 1760, and outlines the laws and regulations that were promulgated to control their activities. Two chapters are devoted to the middlemen's function in the corn and corn products trades and in the animal and animal products trades.

Report of the trade and commerce of Chicago, 1914 (*Ann. Rpt. Bd. Trade Chicago*, 57 (1914), pp. XLII+196+139, figs. 2).—This report gives statistical data showing prices and movement of agricultural produce and provisions in Chicago. It also contains the rules and by-laws of the Chicago Board of Trade.

Farm-machinery trade associations (*U. S. Dept. Com., Bur. Corporations, Farm-Machinery Trade Assoc.*, 1915, pp. XVI+368).—This report describes the activities of the associations connected with the farm machinery trade in their attempts to fix wholesale prices, establish uniformity in production and in cost accounting, influence legislation, restrict retail trade to retail dealers, and prevent price cutting. The report points out that many of these activities have been proper for the protection of legitimate interests, but claims there are others of doubtful legality which have had a tendency to limit competition and enhance prices.

Efforts of communities in the United States toward the control of the high cost of living, G. NESTLER-TRICOCHÉ (*Ann. Rég. Directe [Switzerland]*,

6 (1913-14), No. 55-57, pp. 96).—The author has summarized in this article the various means that are being employed by the national, state, and municipal authorities to solve the problem of the high cost of living.

The question of food supply during the war, E. THÉRY (*Jour. Soc. Statis. Paris*, 56 (1915), No. 6, pp. 230-244).—This article gives data as to the foreign trade in, and the quantity available for consumption of, grain and meat for France, the United Kingdom, Germany, and Austria-Hungary, for 1914, with comparisons for 1913.

Monthly crop report (*U. S. Dept. Agr., Mo. Crop Rpt.*, 1 (1915), No. 4, pp. 29-40, fig. 1).—This number gives the usual monthly estimates of the acreage, condition, and yield of the more important agricultural crops, the farm prices of important products, and the range of prices at important markets, with miscellaneous data.

The estimated percentage of the 1914 cotton crop sold monthly by producers was as follows: August 1.2 per cent, September 6.8, October 14.8, November 18.0, December 16.1, January 11.0, February 8.3, March 7.7, April 6.1, May 2.5, leaving 7.5 unsold on June 1.

The exports of durum wheat for the year ended June 30, 1915, amounted to 15,231,000 bu., as compared with 11,785,000 for the previous year. The receipts at five leading primary markets were 21,356,000 and 20,625,000 bu., respectively.

Statistical information is given concerning the production of grain and potatoes in Germany for 1912-1914, the percentage of the winter wheat crop thrashed by August 1, the commercial bean production, and the per capita value of the exports and imports of the United States from 1855-1859 to 1910-1914.

Moisture determinations made by the Office of Grain Standardization of 678 samples of hard and soft red winter wheats show an average of 14.2 per cent, 10 per cent of the samples exceeding 16 per cent. This is attributed to the frequent rains, and the need of careful handling is pointed out.

Statistical report of the California State Board of Agriculture, 1914 (*Statis. Rpt. Cal. Bd. Agr.*, 1914, pp. XXIV+365, pl. 1).—This report contains a number of statistical tables showing, for a series of years and by counties, the area and production of the principal agricultural crops and facts concerning irrigation enterprises.

The agriculture of Pike County, Illinois, J. MAIN (*Ithaca, N. Y.: Author*, 1915, pp. 25, figs. 4).—This pamphlet describes the climate, topography, soil, market facilities, population, and types of farms and farming, and indicates how the agricultural conditions of the county may be improved.

Studies in the industrial resources of Texas, edited by L. H. HANEY (*Bul. Univ. Tex.*, No. 3 (1915), pp. 105, figs. 21).—This bulletin contains the following articles concerning the industrial resources of Texas: Economic Comparison of Texas Soil Belts, by L. H. Haney; The Climate of Texas in Relation to its Crops, by A. Deussen; Maps Showing Seasonal Distribution of Temperature and Rainfall, by W. T. Donaldson; The Population of Texas and Its Potentialities as a Labor Force, by W. E. Leonard; The Principal Crops of Texas, by A. B. Cox; Cotton Seed Products, by W. D. Wright; The Lumber Industry of Texas, by C. Lohman; Irrigation in Texas, by B. L. Parten; The Railway Service in Texas, by R. Randolph; A Summary of the Banks of Texas, by F. L. Vaughan; and The Wealth of Texas, by R. Myers.

Agriculture in Argentina—national wealth prostituted, G. T. HOLM (*Buenos Aires: G. Krieger*, 1914, pp. 30, fig. 1).—The author believes that the introduction into Argentina of grain elevators would bring about more economical methods of handling their grain, provide the farmer with better credit, and improve the quality of the grain. This publication is written as an argument in favor of their introduction.

Acreage and live stock returns of England and Wales (*Bd. Agr. and Fisheries [London], Agr. Statis., 49 (1914), No. 1, pp. 115*).—This report points out the changes in the number of farms by sizes and the areas devoted to specific crops, and gives detailed statistics by counties for 1913 and 1914 for the total acreage under crops and grass, arable land, and permanent grass, and the number of live stock. Comparative data are given for earlier years for the major subdivisions.

Statistical yearbook of the Union of South Africa, 1912-13 (*Statis. Year Book Union So. Africa, No. 1 (1913), pp. XI+383*).—Among the data included in this yearbook are those relating to the population of the urban and rural districts, number of persons employed in agricultural pursuits, extent of land under cultivation, yield of the principal crops, number of live stock, and number of agricultural implements and machines, according to the census of 1911.

Agricultural statistics of India, 1912-13 (*Agr. Statis. India, 29 (1912-13), I, pp. IX+415, pls. 4*).—This report contains the same items as previously noted (*E. S. R., 31, p. 191*), and adds data for the 1912-13 crop year.

AGRICULTURAL EDUCATION.

Agricultural education and agricultural prosperity, A. C. TRUE (*Ann. Amer. Acad. Polit. and Soc. Sci., 59 (1915), No. 148, pp. 51-64*).—The author discusses the economic and social conditions of farm life in this country, points out as the fundamental need for their improvement a better system of education, including industrial and vocational instruction, and briefly surveys the history and present status of agricultural education in this country. At this present stage of development he recommends that special stress be laid on "the provision of suitable means for the scientific and practical training of teachers of agriculture and home economics for the elementary and secondary schools and of the county agents and other extension workers; adequate supervision of the teaching of agriculture and home economics in the rural elementary and secondary schools by trained experts connected with the state departments of education who thoroughly understand the problems of country life; the encouragement of the consolidation and grading of rural elementary schools with a view to the more efficient organization and equipment of practical instruction in agriculture and home economics, as well as their general improvement as educational agencies . . . and the use of state funds to aid in the establishment of high schools in rural regions, in which agriculture and home economics shall be taught by teachers trained along these lines, or the introduction of efficient courses in these subjects in general high schools frequented by country boys and girls." In his opinion this system of agricultural education will do much toward making farming more profitable and will also greatly increase agricultural production.

Requirements for standardized elementary schools (*Columbus, Ohio: State Supt. Pub. Instr., 1914, pp. 14*).—This bulletin, which has been prepared by the supervisors of agricultural education of Ohio, contains the recent law on the standardization of elementary schools in Ohio which includes requirements for agricultural apparatus to the value of at least \$15 for one-room rural schools of the first grade; at least 2 acres of land for play and agricultural experiment, one teacher employed for 10 months a year, giving a part of his time to the teaching of agriculture or domestic science, or both, and to the supervision of agricultural and domestic art work during part of the vacation, and agricultural apparatus to the value of at least \$25, for consolidated elementary schools of the second grade; buildings hereafter constructed to have at least one acre of land for agricultural and school garden-

ing purposes, a course in domestic science, two teachers employed for 10 months each, teaching, respectively, agriculture and domestic science during the term and supervising it during part of the vacation, and agricultural and domestic science apparatus to the value of at least \$100, for consolidated elementary schools of the first grade. Price lists of agricultural apparatus are included.

The nature-study situation in the elementary schools of Illinois for 1914-1915, FLORENCE G. BILLIG (*Nature-Study Rev.*, 11 (1915), No. 5, pp. 255-259).—Data received from 99 schools are summarized and show that 83 of the schools reporting are teaching nature study. Of these 49 pursue organized courses, 10 have nature study supervisors, 49 teach nature study throughout the year, 43 teach it in grades 1-8, 9 in grades 1-6, and 14 in grades 1-4, the average time devoted to the subject being 50 minutes a week. Twenty-six schools include physiology in the nature study course. The author concludes, in so far as these schools are representative of the work done in Illinois, that nature study has a definite place in the curricula of the elementary schools of Illinois, that there is uniformity in the courses of study, and that physiology is considered a part of the nature-study course.

Sectional report of commissioner regarding agricultural schools and their place in a coordinated system of education in Great Britain, the Continent of Europe, etc., A. C. CARMICHAEL (*Sydney, N. S. W.: Min. Pub. Instr., 1915, pp. 19*).—This is a report by the minister of public instruction of New South Wales on the agricultural schools and their place in a coordinated system of education, based upon personal observations, in Switzerland, Germany, France, and Great Britain; on features of agricultural instruction in Denmark, Ireland, Canada, and the United States; and on the agricultural education requirements of New South Wales comprising (1) nature study and school gardening in the elementary schools for children up to their thirteenth year; (2) the rural consolidated day schools with an agricultural "top," for pupils from 14 to 17 years of age, and possessing about 5 acres of land, to serve as the elementary school and the social center for the district and to give instruction in home economics and the elements of agricultural science with a certain amount of practical work, each pupil working a portion of his father's farm; (3) the agricultural high school, outside of town areas, with from 80 to 100 acres of land, mainly for residential pupils from 14 to 17 years of age, offering a 2-year course in agriculture leading to the agricultural college, one-third of the time being devoted to science with special reference to farm needs and one-third to field work; (4) the agricultural college; and (5) the university school of agriculture.

Fourteenth annual general report of the Department of Agriculture and Technical Instruction for Ireland (*Dept. Agr. and Tech. Instr. Ireland, Ann. Gen. Rpt., 14 (1913-14), pp. VI+182+348*).—This is a report on the department's administration and funds and on details of its work during 1913-14, including agricultural and technical instruction.

Agricultural education and research (*Rpt. Bd. Agr. Scot., 3 (1914), pp. XXIV-XXXII*).—This is a report on progress in 1914 in agricultural education and research work under the control of the Board of Agriculture of Scotland.

A list of agricultural and horticultural officials, institutions, and associations (*Dept. Landb., Nijv. en Handel [Netherlands], Verslag. en Meded. Dir. Landb. No. 2 (1915), pp. 125*).—This list contains the organization and personnel of the Direction of Agriculture of the Department of Agriculture, Industry, and Commerce, including agricultural education and research institutions, agricultural and horticultural winter schools, itinerant instructors, and associations in The Netherlands.

Instruction in moor culture at the agricultural and technical high schools and universities in Prussia, H. WOLFF (*Mitt. Ver. Förd. Moorkultur Deut. Reichs*, 33 (1915), No. 9, pp. 243-246).—The author briefly reviews the lectures and exercises given in rural engineering, including moor culture, together with the number of hours devoted to it in the high schools and universities of Prussia. Only the agricultural high school of Berlin and the University of Halle offer special lectures in moor culture, the other institutions giving only a brief survey of it as a branch of rural engineering.

The essentials of agriculture, H. J. WATERS (*Boston: Ginn and Co., 1915*, pp. X+455+XXXVI, pls. 3, figs. 226).—This text presents the principles underlying successful farm practice in all sections of the United States, the arrangement of the subject matter being based on experience in teaching agriculture in secondary schools and the courses of study adopted by various state departments of education. The author has been assisted by experts in each branch of the subject, which comprises a study of plant production in general and of individual farm crops, care and management of soils, live-stock production, business aspects of farming, and mechanical power for the farm. Each chapter concludes with a list of review questions and problems, practical exercises, and references to literature. Appendixes include score cards, data as to quantity of seed to sow per acre, and similar useful information.

Correlating agriculture with the public school subjects in the Northern States, C. H. LANE and F. E. HEALD (*U. S. Dept. Agr. Bul. 281 (1915)*, pp. 42, figs. 6).—This bulletin gives detailed suggestions to public school teachers on utilizing home projects in correlating agriculture and farm problems with the regular school work, the material being arranged according to a monthly sequence plan. Directions for organizing a club, awarding prizes, and conducting a school-exhibit day are included.

Agronomy, II, Field crops for New Hampshire, G. H. WHITCHER (*N. H. Dept. Pub. Instr., Inst. Circ. 21 (1914-15)*, pp. 22, figs. 4).—Directions are given for conducting a 7-year practical crop rotation, suited to the needs of a large majority of New Hampshire farmers, as a high-school project. The material is so arranged that each crop in the series may be taken up by itself apart from its relation to the rotation as a whole.

Soil bacteriology laboratory manual, P. S. BURGESS (*Easton, Pa.: Chemical Publishing Co., 1914*, pp. VIII+123, figs. 3).—This series of exercises, as used in the College of Agriculture of the University of California, is designed to cover one semester's work of 9 to 10 hours a week, references being appended to each exercise. Appendixes contain general information on subsidiary methods in connection with the exercises.

How can the teacher make bee culture a school subject, training in habits of investigation and arousing an interest in the insect world, E. F. PHILLIPS (*Better Schools*, 1 (1915), No. 6, pp. 96-98).—The author discusses the availability of bees for school purposes and the value of the subject of bee keeping as an introduction to entomology.

Productive swine husbandry, G. E. DAY (*Philadelphia and London: J. B. Lippincott Co., 1915*, pp. XIII+363, pl. 1, figs. 95).—This text which has been previously noted (*E. S. R.*, 29, p. 872), has been brought up to date and widened in scope to adapt it also to Southern conditions.

Pig club manual, J. D. McVEAN (*North Carolina Sta. Circ. 26 (1915)*, pp. 31, figs. 10).—This manual for pig club members contains a brief history of the pig club movement, the aims and duties of pig club members, rules and regulations for club contests, instruction in raising pigs, a pattern and directions for making a bulletin case, and duplicate record blanks which are to be filled in and the completed records sent to the state agent at the close of the year. After the

records have been inspected, graded, recorded, and corrected they are returned to the club members submitting them.

Farm shop work, G. M. BRACE and D. D. MAYNE (*New York: American Book Co., 1915, pp. XII+291, figs. 251*).—Projects in woodworking, blacksmithing, cement and concrete work, and harness making, including the care and use of tools, are outlined for pupils in practical art classes in rural elementary and secondary schools. The work deals in a very practical way with the repair and construction of things used in actual farm work.

Home economics in the public schools of Louisiana, R. MYRTLE BILLINGS (*Univ. Bul. La. State Univ., n. ser., 5 (1914), No. 9, pt. 1, pp. 60, pls. 2, figs. 7*).—This bulletin contains a statement of the practical value of home economics; rules governing approved departments of home economics receiving \$400 state aid; requirements as to qualifications and duties of teachers; a course of study, outlined by months, for approved departments of home economics for grades 8 to 11, inclusive, and equipment; a suggestive course of study for the sixth and seventh grades of rural schools, together with equipment at a minimum cost of \$100; and lists of publications for reference and supplementary reading and of educational exhibits furnished free by commercial firms.

Practical application of cooking lessons given in the running of a regular cafeteria with report of social work in connection with continuation school work in Kenosha, LAURA E. HAHN (*Bul. Wis. Bd. Indus. Ed., No. 9 (1914), pp. 17, figs. 6*).—An account is given of the preparation and serving of the noonday lunch by the cooking class of the Kenosha continuation school and of the social work in connection with the school.

Outline of home economics for club study (*Agr. Col. Ext. Bul. [Ohio State Univ.], 10 (1915), No. 9, pp. 44*).—This outline consists of four parts, viz, food, shelter, clothing, and management, including suggestive topics and references to literature.

Material supplied to boys' and girls' clubs and rural schools (*Agr. Gaz. Canada, 2 (1915), No. 7, pp. 669-677*).—This is a series of summarized statements of material supplied this season to the rural schools, to boys' and girls' clubs, to junior farmers' institutes, etc., by various agencies in Nova Scotia, Ontario, Manitoba, Saskatchewan, and British Columbia.

Twelve projects for Michigan clubs and a short primer on club work, E. C. LINDEMANN (*Mich. Agr. Col., Ext. Div. Club Bul. 1 (1915), pp. 7, fig. 1*).—General information is given to club leaders on methods of conducting corn, potato, apple, live stock, poultry, and market gardening projects for boys' clubs, and housekeeping, garment making, canning and marketing, gardening and canning, poultry, and market gardening projects for girls for 1915.

How to carry out the bean-growing project, J. F. COX (*Mich. Agr. Col., Ext. Div. Club Bul. 3 (1915), pp. 7, fig. 1*).—This bulletin contains the requirements for the bean-growing project, instructions for the growing and care of beans, and a brief discussion of bean diseases, field selection of seed beans, and varieties.

Girls' club work in Georgia, 1915, LOIS DOWDLE (*Bul. Ga. State Col. Agr., No. 86 (1915), pp. 16, figs. 6*).—This bulletin contains information concerning the organization and rules for conducting girls' club work, some results of the work in 1914, and suggestions for making booklets.

Proceedings of the eighteenth annual meeting of the American Association of Farmers' Institute Workers, edited by L. R. TAFT (*Proc. Amer. Assoc. Farmers' Inst. Workers, 18 (1913), pp. 99*).—A detailed report of the proceedings of the meeting held at Washington, D. C., November 10-12, 1913.

Among the papers presented are the following: The Organization of the Institute by the Federal Government in Cooperation With the States for

Demonstration of Improved Methods, by T. A. Hoverstad (pp. 40-42); The Local Unit for Institute Organization, by E. C. Johnson (pp. 44-48); The Obligation of the Farmers' Institute to the Country Woman, the Country Boy, and the Country Girl, by W. J. Kennedy (pp. 49-52); The Obligation of the Farmers' Institute to the Farm Laborer and Tenant Farmer, by E. Van Alstyne (pp. 55-57); The Proportion of State Institute Funds That Should Go to the Support of Institutes for Women, by Mrs. W. N. Hutt (pp. 61-63); Model Equipment for a Local Institute for Women, with a Model Program, by Helen L. Johnson (pp. 63-68); How the Organizing of Local Institutes for Women Can Best Be Effected, by Mrs. H. M. Dunlap (pp. 71-74); The Advisability of the Organization of a Section for Women in the American Association of Farmers' Institute Workers, by Ida S. Harrington (pp. 75-78); and How Can Greater Local Self-Dependence be Secured in Institute Work? by W. D. Hurd, pp. 83-85).

Proceedings of the nineteenth annual meeting of the American Association of Farmers' Institute Workers, edited by L. R. TAFT (*Proc. Amer. Assoc. Farmers' Inst. Workers, 19 (1914), pp. 123*).—A detailed report of the proceedings of the meeting held at Washington, D. C., November 9-11, 1914, and previously noted (*E. S. R., 32, pp. 14, 97*).

MISCELLANEOUS.

Annual Reports of Virginia Station, 1913 and 1914 (*Virginia Sta. Rpts. 1913-14, pp. 169, figs. 34*).—This contains the organization list, a report of the acting director as to the organization, publications, finances, work, and other data pertaining to the station, financial statements for the fiscal years ended June 30, 1913, and June 30, 1914, departmental reports, and reprints of Technical Bulletins 1-4, previously noted, and of Technical Bulletins 5-8, abstracted elsewhere in this issue.

Monthly bulletin of the Western Washington Substation (*Washington Sta., West. Wash. Sta. Mo. Bul., 2 (1915), No. 11, pp. 20, figs. 9*).—This number contains brief articles on the following subjects: Celery Culture in Western Washington, by J. L. Stahl; Late Blight of Celery, by H. L. Rees (see p. 742); and Concerning Abnormal Eggs, The Development of an Egg, and The Feed Requirements of a Laying Hen, by V. R. McBride.

Experiment station research as seen from within and without, H. J. WHEELER (*Proc. Soc. Prom. Agr. Sci., 35 (1914), pp. 38-46*).—This article has been previously noted (*E. S. R., 32, p. 97*).

The small field laboratory and its atmosphere of research, D. FAIRCHILD (*Proc. Soc. Prom. Agr. Sci., 35 (1914), pp. 62-71*).—This article has been previously noted (*E. S. R., 32, p. 306*).

Agricultural encyclopedia, compiled by K. ZU PUTLITZ and L. MEYER (*Landw. Enklop. Stuttgart: Deut. Verlags Anst., 1911, vols. 1, pp. VIII+800; 2, pp. 800; 1912, vol. 3, pp. 800; 1913, vols. 4, pp. 800; 5, pp. 800; 1914, vol. 6, pp. 518, pls. 232, figs. 1221*).—This is a general reference work, with special prominence given to subjects pertaining to agriculture, forestry, horticulture, agricultural industries, agricultural laws and their administration, etc.

NOTES.

California University and Station.—Construction is being begun on the laboratory building to cost \$100,000 which is to be erected on the new 465-acre tract at Riverside for the use of the Citrus Substation and Graduate School of Agriculture.

Donald Bruce, formerly supervisor of the Flathead National Forest of Montana, has been appointed assistant professor of forestry and assistant forester in the station. Walter C. Dean, a 1915 graduate of the college of agriculture, has been appointed assistant in the department of soil technology of the station, vice Robert Pendleton, resigned September 1.

Delaware College.—The college has recently received \$500,000 from a donor who wishes his name withheld. Of this sum \$225,000 will be used for a building to house the entire activities of the departments of agriculture, general chemistry, and biology; \$75,000 to remodel the old main building, which will house the social activities of the college; and the remainder will be invested as an endowment fund. The men's college opened in September with 232 students in attendance, 75 of whom are in agriculture. The women's college, which has just received its second class, has 90 students in attendance.

Kansas College and Station.—Edward C. Johnson, superintendent of institutes and demonstrations, has been appointed dean of the division of college extension. M. G. Burton has succeeded J. C. Werner, resigned, as director of correspondence work. Theodore Macklin has succeeded E. D. Baker, resigned, as instructor in rural economics. W. A. Etherton, specialist in rural architecture in this Department, has been appointed professor of rural architecture, and Miss Nola Treat assistant professor of domestic science.

Other appointments include M. F. Ahearn as professor of landscape gardening; David Gray, assistant animal husbandman; Helen Hahn, assistant professor of home economics and education; Carl S. Hoar, instructor in botany; A. E. McClymonds, assistant instructor in agronomy and superintendent of the agronomy farm; Frank E. Mussehl, assistant in poultry husbandry; N. E. Olson, assistant in dairy husbandry; Kurt Peiser, assistant in bacteriology; Dr. C. A. Pyle and Carl Thompson, lecturers in animal husbandry extension; M. C. Tanquary, instructor and assistant in entomology; J. W. Zahnley, assistant in agronomy; and L. C. Williams, assistant to the superintendent of institutes and demonstrations.

Maryland College.—The total enrollment is 310, with a Freshman class of 91. The college has established a correspondence study department with courses in farm soils, fertilizers and fertility, corn, soy beans and cowpeas, horses and mules, dairy farming, farm poultry, the apple, vegetable gardening, farm bee keeping, food principles and food values, grounds of the farm home, farm sanitation, rural economics, farm accounts, farm dwelling construction, gas, oil, and hot-air engines, and pipe and pipe fittings.

Minnesota University and Station.—John D. Schofield, one of the committee of three members of the Pomona Grange of Hennepin County largely responsible for the establishment of the school of agriculture, died September 18 at the age of 87 years. Recent appointments include the following: Alice M. Bilster as assistant professor of nutrition; Philip S. Jordan as instructor in animal husbandry at Morris; J. T. E. Dinwoodie, as assistant veterinarian; L. V. France as instructor in bee keeping; D. O. Spriestersbach, as research assistant in agricultural chemistry; D. D. Valleau as research assistant in horticulture; Frank J. Piemeisel as research assistant in cereal rust studies; Roswell P. Ingram as seed inspector; and Anna S. Olsen as assistant in home economics at Crookston. W. P. Kirkwood, editor in the station, has also been appointed associate professor of journalism.

Nebraska University.—Contracts have been awarded for the new biology building, which will house the departments of botany and zoology and will bear the name of Bessey Hall. The structure will consist of a 3-story and basement main building, 235 by 75 feet, with a short wing at each end and attached greenhouse and vivaria, and will cost approximately \$200,000.

The new agricultural engineering building is to be a two-story and basement structure, 180 by 70 feet, with a one-story annex 140 by 90 feet.

C. L. Burlingham, extension specialist in dairying has resigned to accept a position with the Dairy Division of this Department, and has been succeeded by D. H. Propps as extension assistant professor of dairy husbandry. L. M. Gates has resigned as field expert in entomology to engage in farming. Other appointments include the following: M. E. Dickson as assistant professor of poultry husbandry, beginning November 1; P. L. Gaddis as assistant professor in agronomy; R. E. Holland, assistant in instructional agronomy; K. F. Warner as extension specialist in animal husbandry; Miss Emma Ort as extension specialist in home economics; and E. G. Maxwell as extension instructor in dairy manufactures.

Nevada University and Station.—The state hygienic laboratory has been separated from the department of bacteriology and veterinary science of the station and now occupies quarters in another building. Sheds and a corral have been erected on the waste land at the north end of the station farm for the study of the possibility of developing an anthrax serum. Plans are being drawn for a field hospital for the study of animal diseases, to be constructed on the station farm. G. G. Schweis, assistant in entomology, resigned August 1, and August Holmes, assistant in chemistry, about September 15, the latter to complete post-graduate work at Johns Hopkins University.

New Mexico College and Station.—Fred C. Werkenthin has been appointed professor of botany and station botanist, vice J. M. Mann, resigned. Dr. Louis Allen Higley has been appointed station chemist and professor of chemistry, vice Dr. R. F. Hare, whose resignation has been previously noted. L. R. McNeely, assistant agronomist, resigned July 1 and was succeeded August 20 by James T. Barlow. R. L. Stewart, assistant animal husbandman in the station, has been transferred entirely to instruction work. George W. Kable, assistant irrigation engineer, resigned July 1.

Cornell University.—The registration in the college of agriculture is over 1,600, an increase of more than 50 over the previous year. Arrangements have been completed whereby five members of the 1916 class may obtain experience in teaching agriculture by serving for one term as assistants to teachers of agriculture in the high schools of the State. They will receive a compensation sufficient for expenses and will be given three credit hours for the work.

Alice Gertrude McCloskey, a 1908 graduate and assistant professor of rural education, died October 19. Recent appointments include the following: Albert

R. Bechtel, whose resignation from the Pennsylvania College and Station has been previously noted, and J. Marshall Brannon, as instructors in botany; Wallace R. Chandler as instructor in parasitology; Dr. W. T. M. Forbes as instructor in entomology; C. H. Guise as instructor in forestry; Edward Riley King as assistant professor of bee culture; J. C. McCurdy as instructor in farm engineering; William E. Mordoff as instructor in farm mechanics; Gilbert W. Peck as instructor in pomology; J. R. Schramm as assistant professor in botany; and Roy Glenn Wiggins as instructor in farm crops. C. E. Ladd, of the department of farm management, has been appointed director of the New York State School of Agriculture at Delhi.

Ohio State University and Station.—Correspondence courses in agriculture are being offered for the first time, 22 of these courses being announced. The registration numbers over 150.

John F. Cunningham, of Cleveland, and John Kaiser, of Marietta, have been appointed to the governing board of the university. Dr. Alfred Vivian has been appointed dean of the college of agriculture, Clark S. Wheeler, director of agricultural extension, and George W. Bush, state leader of county agents with headquarters at the college of agriculture. Other appointments include Dr. Paul L. Vogt, professor of sociology at Miami University, as professor of rural economics; Milligan C. Kilpatrick as instructor in poultry in the extension department beginning October 1; Ivan McKellip as field agent in cow testing; S. M. Salesbury, instructor in animal husbandry and dairying in the North Carolina College, as assistant professor of animal husbandry; P. H. Elwood, of the Massachusetts College, as assistant in horticulture; and Virgil Overholt as instructor in agricultural engineering in the extension service. N. R. Elliott, assistant in horticulture, has accepted an appointment as assistant horticulturist in the Kentucky University and Station.

In the station, B. S. Davison has been appointed assistant in soil biology and W. C. Boardman assistant in the soil survey.

Oregon College and Station.—The Withycombe Animal Husbandry Club, named in honor of Governor James Withycombe, formerly director of the station, has been organized by the students of the animal husbandry department to establish closer relations with their instructors and the practical livestock men of the State.

Recent appointments include the following: W. J. Gilmore, of the Manitoba College, as assistant professor of farm mechanics, vice E. M. D. Bracker, resigned to engage in farming in Illinois; A. C. McCulloch, instructor in animal husbandry at the Ontario College, as instructor of poultry husbandry, vice A. G. Lunn; Roy E. Marshall as instructor in horticulture; L. Eugene Robinson, a graduate in architecture in the University of Pennsylvania, as instructor in rural architecture; and H. A. Vickers as secretary of college extension, vice Paul M. Collins. A. L. Lovett, associate professor of entomology, has been appointed acting head of the department of entomology of the college and station, vice H. F. Wilson, whose resignation is noted elsewhere.

Wisconsin University and Station.—A special field course in farm management was offered at the college of agriculture from June 21 to July 30. The class of about 12 students was quartered in tents pitched in successful farming regions, and gave considerable time to observing the farm practice in the vicinity.

Under a new law, the state department of agriculture has been reorganized with C. P. Norgord, superintendent of farmers' institutes, at its head. It now consolidates the former department of agriculture, which had under its control the management of the state fair; the state board of immigration; the state live stock sanitary board, which had control of infectious animal diseases; and

the state apiary inspection; and by transfer from the College of Agriculture the nursery and orchard inspection, as well as the inspection of insecticides and fungicides. J. G. Sanders has resigned as head of the department of entomology to become state entomologist; Dr. S. B. Fracker, instructor in entomology, to become deputy nursery inspector; and C. E. Lee, as assistant professor of dairy husbandry and dairy husbandman, to become dairy specialist for the state dairy and food commission. H. F. Wilson, entomologist at the Oregon College and Station has succeeded Professor Sanders, and G. H. Benkendorf, Professor Lee.

F. B. Morrison, assistant to the dean, has been made assistant director of the station. W. A. Sumner, assistant in agricultural journalism at the Kansas College, has been appointed editor of station publications. The last legislature reduced the annual appropriation for station publications from \$17,000 to \$10,000.

Prospective Agricultural Meetings.—The sixty-eighth meeting of the American Association for the Advancement of Science will be held in Columbus, Ohio, from December 27, 1915, to January 1, 1916. Section M (Agriculture) will be addressed by its vice-president, L. H. Bailey, on *The Forthcoming Situation in Agricultural Work, part 2*. The section has also arranged a symposium on *The Relation of Science to Meat Production*.

The American Association of Economic Entomologists, the Entomological Society of America, the Botanical Society of America, the American Phytopathological Society, the Society for Horticultural Science, and the Association of Official Seed Analysts of North America are among the affiliated societies which are to meet with the association.

The seventh annual meeting of the American Association of Agricultural Engineers will be held in Chicago, December 28–30.

American Association for the Advancement of Agricultural Teaching.—The sixth annual meeting of this association was held in Berkeley, Cal., August 10.

A report of the standing committee on *The Use of Land in Connection With Agricultural Teaching*, prepared by the States Relations Service of this Department, was based upon a study of the home-project method as followed in teaching agriculture in the secondary schools of New York. In this method each pupil chooses a project for home study before March 1, and after this date most of the time set aside for laboratory work is devoted to the projects. Part of the time is spent in school in reference reading, the drawing of plans, and such other work as may be done to advantage, and as the summer approaches the project work gradually replaces class work.

The home-project plan is so new in agricultural instruction that many phases of its application are still in process of development. Among these are its relations to the school course in agriculture, the basis upon which credit should be given, and the relation of the home project to club work.

The home-project plan is considered a promising means of bringing the home and school together in educational problems. To be effective, however, hearty cooperation should exist between parents and teachers; just how to secure this cooperation is still a problem.

Projects may be grouped according to their chief aim, as production projects, the chief purpose of which is to produce an agricultural product at a profit; demonstration projects, where the chief aim is to demonstrate improved methods or materials; experimental projects, where there is uncertainty as to results; or improvement projects, where students may undertake the improvement of plants and animals, the home grounds, or the farm in general with little hope of immediate returns. There is thus a distinction between a project, the principal aim of which is profit, and those having other aims predominating, and the question arises as to which class of projects are most desirable from an educational point of view.

Inasmuch as proper supervision is admitted to be one of the most important factors in a successful project, and the critical time for most projects comes in the summer, high schools that do not employ teachers of agriculture for the full year are placed at a disadvantage. Lack of training on the part of teachers is another obstacle and brings up the question as to whether college courses in agricultural education should give special training for project work.

W. G. Hummel, in a paper on Greater Uniformity in High School Agriculture, enumerated the following advantages: (1) The eliminating of "freak" courses and valueless exercises and the inclusion of essentials duly proportioned; (2) the betterment of the science courses, making possible organized correlation of agricultural topics with the other branches of study, as for example, between farm mechanics and physics in the last high school year; (3) state aid can be allotted with greater fairness and effectiveness; (4) agricultural colleges can better define and grant adequate credits for high school agricultural work; and (5) students can more readily transfer from one school to another. In summing up his paper Professor Hummel declared that "there is no reason why agricultural work in the high school can not make better men and better citizens as well as better farmers and better farming."

Supervised Observation and Experience in the Preparation of Secondary Agricultural Teachers was the subject of a paper by K. L. Hatch. In this he discussed the academic, technical, and professional training of the prospective teacher of agriculture in high schools, favoring as requirements graduation from a standard college and a professional preparation equivalent to fifteen semester hours credit which should include three semester hours credit in special method and three in practice teaching. Three methods of giving practice teaching are being utilized by agricultural colleges: (1) The moot court, (2) the use of nearby schools, and (3) practice in teaching short courses in secondary and collegiate institutions. In the moot court and nearby school methods of practice teaching, however, the work is too limited, impossible to supervise properly, difficult of administration, disruptive of regular classes, and is artificial. The paper therefore held that the most satisfactory method of giving supervised practice teaching in departments of agricultural education in land-grant colleges is through secondary schools connected with the colleges and teaching in college short courses.

In a paper entitled Some Difficulties and Failures in Teaching Agriculture in Secondary Schools, Milo N. Wood pointed out that the school board of the community often expects too much in the way of immediate results or demands that the work show a handsome financial profit. Frequently the difficulty lies with the unpreparedness of the teacher for his work. Agricultural teachers are sometimes expected to teach too many side lines, such as arithmetic, chemistry, physics, music, drawing, and athletics, and time may be wasted in nonessentials, particularly in laboratory and school farm work.

G. A. Bricker discussed The Content of the Course in Special Methods of Teaching Public School Agriculture. In his opinion, standardization with reference to the content of these courses should now be possible, although there will be variations such as those due to the character of the local agriculture, the educational laws of the State, the scheme of scholastic organization within the institution offering the course, and the personality of the educator who is charged with its administration. By common consent, however, the course should include class room, laboratory, and field methods, the literature of the subject, including reference matter and school texts, the adaptation of special methods that are used in other school subjects, and an outline of definite and concrete topics showing their proper sequence of presentation and their relative importance to each other and to the course as a whole.

There is now believed to be material of sufficient importance to justify a course of at least two collegiate hours' value.

The officers elected for the ensuing year are A. V. Storm, University of Minnesota, president; W. H. French, Michigan Agricultural College, vice president; and A. C. Monahan, U. S. Bureau of Education, secretary.

Agriculture at the National Education Association.—Rural and agricultural education received unusual attention at the meeting at Oakland, Cal., August 16-28.

In a paper before the Department of Rural and Agricultural Education, C. H. Lane defined the meaning of high school extension work in agriculture. This comprises all educational efforts at the homes and on the farms of the people and also such work at the school itself as centers directly in interests away from the school. Community work in agriculture is, he deemed, a necessary part of the school that is maintained by the people for the service of the people. He maintained that before attempting extension work, however, the teacher should study the agriculture of the community, the character of the soil and improvements, systems of farming, the class of farmers, and the condition of the rural one-teacher schools and of the churches. The teacher may then extend his work by supervising the home project work with his pupils, directing agricultural instruction in the grades, organizing and following up boys' and girls' clubs, acting as organizer for the one-week short course for farmers, offering personal counsel and advice on certain days to farmers of the community, assisting and organizing farmers' reading courses, directing school agricultural exhibits locally and at the county fair, and through Saturday meetings with farmers and by farm visitation. He should also have an office in the high school in which facts pertaining to the agriculture of the community may be assembled and where they will be available for the use of any person who desires them. The agricultural teacher would thus be an organizer of information and of movements and a director of agricultural enterprises within his school community.

How Boys and Girls Respond to Home Work in a Large City was the title of a paper by George L. Farley, in which he showed the surprising amount of growth and interest in school and home gardening in the city of Brockton, Mass. Four years ago a citizen of the city offered \$25 to start the work and in the fall some 30 children had carried the work to successful completion. This year \$300 was given by citizens in addition to about \$1,000 furnished by the city and over 2,700 pupils carried on gardens. In addition to garden work the work has extended to the forming of poultry clubs, the keeping of bees, and canning clubs.

N. H. Forman read a paper on Gardening and Farming in the Philippine schools, this consisting largely of a review of the progress made in the Philippines along industrial lines since the requiring of industrial work in the public schools in 1905. More than 100,000 pupils were engaged in gardening during the school year of 1914-15 and more than 43,000 pupils had home gardens which were kept producing throughout the year as required school work.

Other papers read before this department were Educational Values of School Credit for Home, Vacation, and Other Out-of-School Work; Boys' and Girls' Demonstration Club Work as Units of Value in School Credit; Agricultural Education in Australia, which consisted largely of a historical review of the development of agricultural education in Australia; Means Now Employed in the United States for the Training of Rural Teachers and the Extent of Such Preparation for Work in Agriculture; and The Preparation of Rural Teachers Through State Colleges of Agriculture for Work in Agriculture, by President H. J. Waters. President Waters maintained that this duty is the function of the

state normal schools, teacher training departments in high schools, and county normal training schools, but that the agricultural colleges can participate through summer schools. As an argument in favor of bringing rural school teachers in contact with the college, he cited the sympathetic atmosphere of the college toward rural life. He presented an adapted secondary vocational course in an agricultural college for the training of rural teachers, in which special attention is given to academic preparation for teaching.

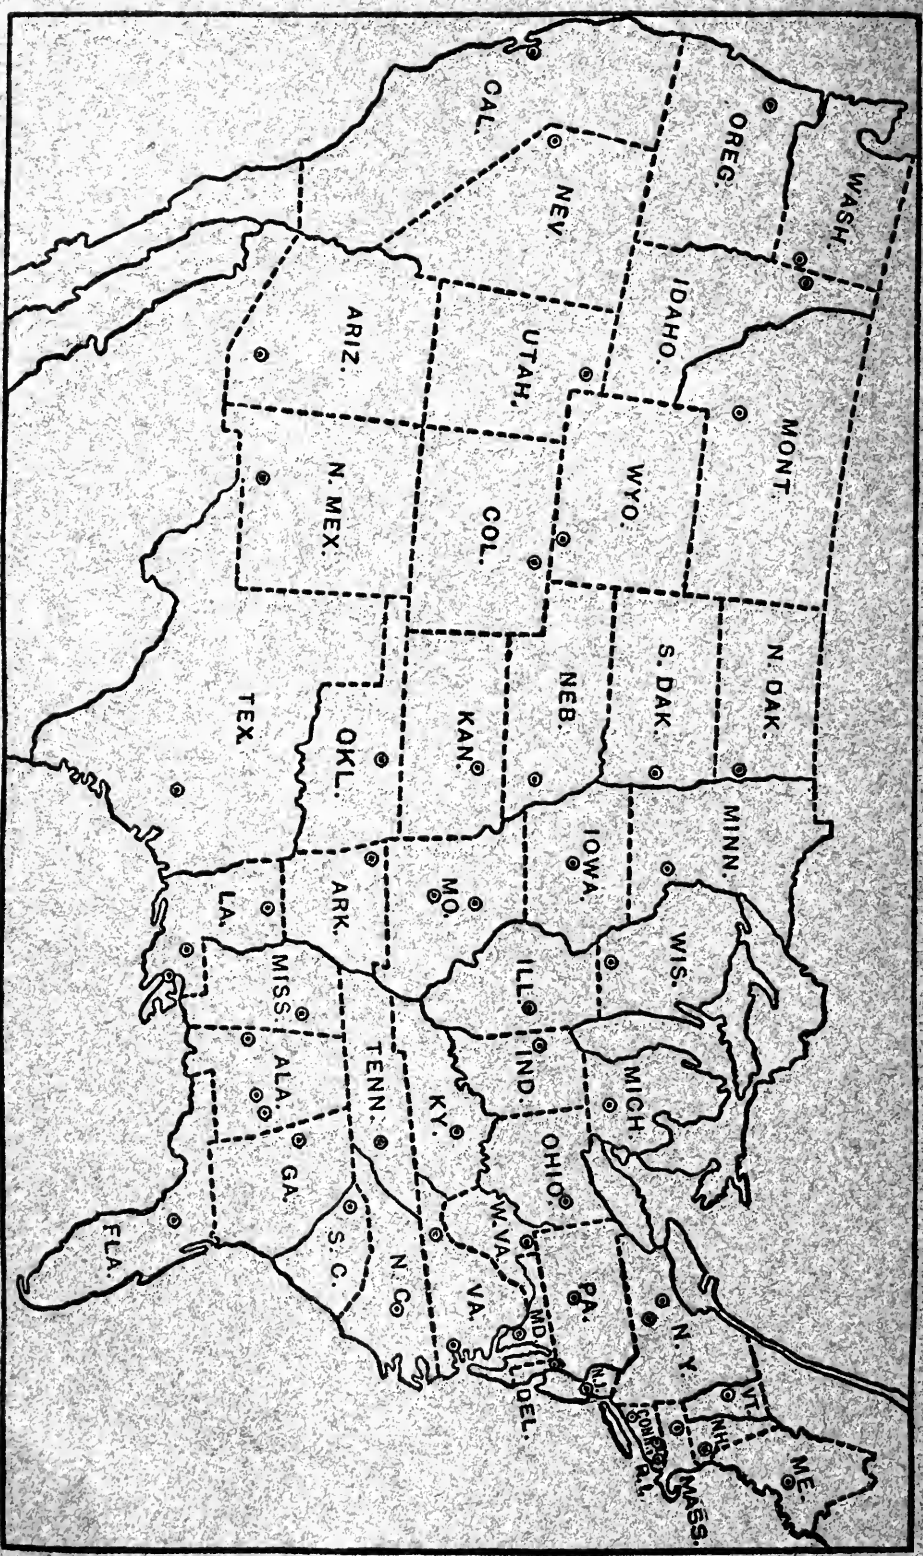

Several years ago a commission of the association on the reorganization of secondary education was established to help bring about a satisfactory articulation of high school and college. This commission contains ten subcommittees, one of which is on agriculture. It has for its aim the working out of the proper kind of high school extension work in agriculture, the general aim of secondary agriculture, the high school agricultural library, and aims, materials, and methods in agriculture below the high school, as well as in poultry husbandry, horticulture, and other lines of secondary agricultural instruction. A round-table conference was held under the direction of the chairman, A. V. Storm, and dealt with the following topics: The High School Extension Work, presented by C. H. Lane; Aims, Materials, and Methods in Agriculture Below the High School, by E. C. Bishop; and The General Aim of Secondary Agriculture, by W. G. Hummel. It is expected that a final report of this subcommittee will be submitted to the full committee at the regular session of the Department of Superintendents in February, 1916.

Agricultural Work in China.—The Chinese Ministry of Agriculture and Commerce was granted last spring over \$100,000 for the establishment of demonstration farms and now has in operation three cotton farms, one sugar plantation, two forestry estates, and three farms devoted to pasturage tests. There is also a model ranch at Chu Chow at North Anhui. A system of extension teaching is also projected, starting with the establishment of an extension school for training traveling lecturers and demonstrators. The employees must be men of practical farm experience in their respective districts and are to work in cooperation with the staffs of the demonstration farms.

The maximum growth of Japanese timber species, Honda.....	844
Loblolly or North Carolina pine, Ashe.....	844
Longleaf pine distinguished visually from loblolly or shortleaf, Koehler.....	844
Tests of timbers treated by wood-preserving processes, Betts and Newlin.....	845
The artificial preservation of mine timbers, Moll.....	845
Study on vegetable ivory, Vignolo-Lutati.....	845

DISEASES OF PLANTS.

Annual report of the botanist and plant pathologist, Stoward.....	845
Mycology, Shaw.....	846
The more important plant enemies and their control, Andersen.....	846
The control of plant diseases in Sweden, Eriksson.....	846
Mercury chlorophenol as a fungicide, Remy and Vasters.....	846
Infection experiments with parasitic fungi, IV, Treboux.....	847
The 1914 outbreak of rust on winter grain in Bavaria, Hiltner.....	847
The cause and prevention of dry spot of oats, Krüger and Wimmer.....	847
Causes predisposing wheat to attack by <i>Erysiphe graminis</i> , Rivera.....	847
A new disease of germinating wheat, O'Gara.....	847
A new alfalfa leaf spot in America, Melchers.....	848
Treatment of beet seed for control of root scab, Kruger and Wimmer.....	848
Celery diseases.....	848
Diseases of crucifers.....	848
Root nodosities of crosses between swedes and turnips, Hedweg.....	848

	Page.
Peppermint rust, Gróí.....	848
Potato diseases, Henning.....	849
Potato diseases.....	849
Blight resistance in potatoes, Hill.....	849
Fusaria of potatoes, Sherbakoff.....	849
The transmission of potato mosaic through the tuber, Wortley.....	850
Powdery scab of potatoes in Oregon, Bailey.....	850
Wart disease of potatoes, Eriksson.....	850
Withering of the panicle in rice, Poli.....	850
A disease affecting the sisal hemp plant, Bancroft.....	850
Leaf spot disease of sisal in German East Africa, Braun.....	851
Occurrence of the bacterial disease of Sudan grass in Utah, O'Gara.....	851
Diseases and enemies of sugar beets and alternating crops in Bohemia, Uzel.....	851
Control of beet nematodes, Müller and Molz.....	851
Sugar cane gummosis, Groenewege.....	851
The new disease or dry disease of the sugar cane, Bancroft.....	852
<i>Thielavia basicola</i> as a root parasite of watermelons in Utah, O'Gara.....	852
Bitter pit, its cause and cure, McAlpine.....	852
The control of bitter pit in the growing fruit, McAlpine.....	852
Canker of fruit trees.....	853
Conditions determining the outbreak of vine mildew in Hungary, von Istvanffi.....	853
Resistance of hybrid direct-bearer vines to mildew, Pée-Laby.....	854
Rose diseases.....	854
Dissemination and growth of chestnut blight fungus, Anderson and Babcock.....	854
Conditions of chestnut attacked by ink disease, Petri.....	854
Forest botany, Parker.....	855

ECONOMIC ZOOLOGY—ENTOMOLOGY.

Economic entomology in the United States of America, Emelianov.....	855
Some present needs in economic entomology, Fernald.....	855
A new air-conditioning apparatus, Dean and Nabours.....	855
Cages and methods of studying underground insects, Davis.....	855

EXPERIMENT STATION RECORD.

VOL. XXXIII.

ABSTRACT NUMBER.

No. 9.

RECENT WORK IN AGRICULTURAL SCIENCE.

AGRICULTURAL CHEMISTRY—AGROTECHNY.

Progress made in the field of agricultural chemistry in the years 1912 and 1913, P. EHRENBURG (*Chem. Ztg.*, 38 (1914), Nos. 99, pp. 1022, 1023; 102-103, pp. 1038, 1039).—A retrospect.

Francis Humphreys Storer, L. W. FETZER (*Biochem. Bul.*, 4 (1915), No. 13, pp. 1-9, pl. 1).—A tribute to the services of Francis Humphreys Storer in the advancement of agricultural chemistry.

Publications of Francis Humphreys Storer, L. W. FETZER (*Biochem. Bul.*, 4 (1914), No. 13, pp. 9-17).—A comparatively complete bibliography of the contributions of Francis Humphreys Storer to the literature on general, technical, and agricultural chemistry.

The chemistry of colloids and some technical applications, W. W. TAYLOR (*London: Edward Arnold, 1915, pp. VIII+328, figs. 22*).—After a general consideration of the topic, the methods of preparation, absorption, and the applications of colloid chemistry to dyeing, tanning, the soil, purification of sewage, and biology are gone into.

The arsenates of lead, R. H. ROBINSON and H. V. TARTAR (*Oregon Sta. Bul. 128 (1915), pp. 3-32, figs. 3*).—After considerable work was done, the Holland and Reed method (E. S. R., 28, p. 308) was not regarded as a safe one to use for the preparation of pure lead hydrogen arsenates, but it was found that fairly pure hydrogen arsenates can be prepared by the use of the reaction between lead nitrate and di-sodium hydrogen arsenate.

All attempts to prepare pure lead ortho-arsenate were unsuccessful. "Lead ortho-arsenate is not formed under the ordinary aqueous conditions employed in the manufacture of commercial lead arsenate, and it is not a component of the commercial material as has been formerly supposed."

Lead pyro-arsenate was prepared by heating lead hydrogen arsenate to a temperature slightly higher than 200° C. As the lead hydrogen arsenate has to be heated to a comparatively high temperature before loss of water occurs, it seemed evident that lead pyro-arsenate is not a constituent of commercial lead arsenate.

Basic lead arsenate is much less bulky than lead hydrogen arsenate. The latter has a very fluffy appearance, similar to that of wheat flour. The basic compound, owing to a tendency of its particles to collect together and settle out more rapidly from suspension, "perhaps prevents its being spread so evenly over the foliage of fruit trees by the usual methods of spraying as can be accomplished with the lead hydrogen arsenate." The specific gravity of lead hydrogen arsenate at from 4 to 20° C. is 5.786 and of basic arsenate is 7.105. Both of the compounds were found to be very insoluble.

"Field tests made by using the pure arsenates at strengths as high as 8 lbs. to each 100 gal. of water were tried for two consecutive seasons with no injury to foliage. The lead hydrogen arsenate was found to react very easily with a number of different substances, especially those of an alkaline nature. On the other hand, the basic arsenate is a comparatively inert material. Tests made with tent caterpillars showed the acid salt to be a much quicker acting poison.

"The necessity of more complete methods for the true valuation of commercial lead arsenates is pointed out. Satisfactory methods have been devised for, and applied to, commercial samples as follows: (a) The estimation of lead hydrogen arsenate in the presence of mixed salts, (b) the determination of lead carbonate, (c) new methods for water-soluble arsenic oxid and water-soluble impurities, (d) a method for acid insoluble impurities, and (e) the detection of acetates and the quantitative estimation of chlorin. The application of these methods shows a wide variation in the composition of the commercial arsenates and gives a better valuation of them than the methods now in use.

"The precipitates obtained from the reactions of lead acetate and lead nitrate with di-sodium hydrogen arsenate under certain conditions are mixtures of lead hydrogen arsenate and the basic lead arsenate. When hydrogen arsenate is mixed with lime-sulphur in the proportions used in field practice, a reaction takes place in which considerable quantities of lead sulphid and calcium arsenate are formed, accompanied by the deposition of free sulphur. Appreciable quantities of arsenic pass into solution due to the solubility of the calcium arsenate. The reaction between lime-sulphur and the basic arsenate is comparatively slight."

Plant pigments, C. J. WEST (*Biochem. Bul.*, 4 (1915), No. 13, pp. 151-160).—A review of the chemistry of plant pigments other than chlorophyll. See also a previous note (E. S. R., 31, p. 427).

The organic phosphorus compounds of wheat bran, C. J. ROBINSON and J. H. MUELLER (*Biochem. Bul.*, 4 (1915), No. 13, pp. 100-117).—The work is divided into three parts. The first section deals with the results of a study of the precipitate obtained by adding copper acetate to an extract of wheat bran; the second, with the material resulting from the alcoholic precipitation of bran extracts; and the third describes a combination of the copper acetate and alcohol precipitation methods.

With Anderson's method (E. S. R., 33, p. 11) a tri-barium salt of phytin was obtained crystalline in structure and identical in properties with that of Anderson, but it corresponded more closely to the formula $C_6H_{15}O_2P_2Ba_3$. Both in the case of the barium salt and the free acid the compounds obtained appeared to contain six more hydrogen atoms to the molecule; while in carbon, barium, and phosphorus contents, they agreed very well with Anderson's compounds.

"There is in addition, a considerable amount of another substance, very similar in composition, the barium salt of which contains only 34 per cent of barium, instead of 38 per cent in barium phytate. The fact that this substance does not dialyze indicates that its molecule is larger than that of barium phytate.

"There is, finally, a compound differing widely from phytin in having more carbon and less phosphorus in the molecule, which by hydrolysis splits off a reducing sugar (pentose), and whose barium salt contains only about 31 per cent of barium. We do not believe the composition of this substance has been definitely fixed. It has not been obtained in crystalline form, the analogous crystalline brucin salt prepared by Anderson probably being simply brucin phosphate."

Some observations on phytin, W. HEUBNER (*Biochem. Ztschr.*, 64 (1914), No. 4-6, pp. 409-421).—The author finds that phytic acid is only gradually cleaved in a 1.5 normal acid solution at 37° C. Less than 1 per cent of the amount present is cleaved per day. Light accelerated the cleavage through acid very much.

The hydrolysis of maltose by hydrochloric acid under the Herzfeld conditions of inversion. A reply to A. J. Kluyver, W. A. DAVIS (*Jour. Agr. Sci. [England]*, 6 (1914), No. 4, pp. 413-416).—"It is shown that contrary to the statements of Kluyver and others, maltose undergoes slight hydrolysis (to the extent of about 2 per cent when 1 per cent solutions of maltose are used) when heated with hydrochloric acid under Herzfeld conditions. It is preferable, therefore, to adopt 10 per cent citric acid, under the conditions formerly laid down, in estimating cane sugar in plant extracts when maltose is likely to be present."

The influence of low temperatures on enzymes, J. S. HEPBURN (*Biochem. Bul.*, 4 (1915), No. 13, pp. 136-150).—A review.

Habituation of lactic ferments to poisons, C. RICHEL (*Rev. Gén. Bot.*, 25 bis (1914), pp. 583-587).—The lactic ferment is found able to accustom itself progressively (as shown by increased acid formation) to solutions of potassium bromid. The optimum of adaptation was obtained at relatively high concentrations of the toxic salt, but if returned to the nonpoisonous mixture it recovered its normal powers in one or two days.

The significance of the amount of low molecular glycerids of fatty acids in milk fat of various animals, E. GUTZEIT (*Kühn. Arch.*, 5 (1914), pp. 127-138).—The Reichert-Meissl number of woman's milk fat was found to be 2.03. This is in agreement with the findings of Laves (2.5) and Pizi (1.42), but not with Sauvaitre (15.8). The Reichert-Meissl number of the fat in cow's, sheep's, and goat's milk is two or two and one-half times greater than the fat in asses' and mare's milk, and in the latter the Reichert-Meissl number is six times as great as in human milk. Pig's and dog's milk contains still less of these volatile fatty acids. Accordingly, it is concluded that herbivorous animals require milk with fat which contains a high water-soluble volatile fatty acid content and the omnivorous and carnivorous animals a milk fat with a low one.

The relation of the excessive amount of fatty acids of cow's milk fat to infantile gastrointestinal disorders is discussed.

The estimation of inorganic phosphoric acid in the presence of phosphoric acid esters, W. HEUBNER (*Biochem. Ztschr.*, 64 (1914), No. 4-6, pp. 401-408).—Inorganic phosphoric acid in the presence of 4 per cent by volume of concentrated sulphuric acid and 15 per cent of ammonium nitrate can be precipitated quantitatively at a temperature of 37° C. within 6 hours as ammonium phosphomolybdate. The presence of small quantities of phytin does not influence the results, but increasing amounts of this substance do. Glycero-phosphoric acid affects the results much less than phytin.

About the calculation factor used in determining phosphorus according to the Neumann method, W. HEUBNER (*Biochem. Ztschr.*, 64 (1914), No. 4-6, pp. 393-400).—Neumann states that 1 cc. of semi-normal sodium hydroxid is equivalent to 1.268 mg. of phosphorus. This factor (0.553) was found too low, 0.57 giving figures more nearly correct. The specifications set down by Neumann and Gregersen must be observed.

On the factor to be used for the calculation of the phosphoric acid in Neumann's method, S. L. JODIDI (*Jour. Amer. Chem. Soc.*, 37 (1915), No. 7, pp. 1708-1710).—In connection with an investigation on the chestnut bark disease, a careful redetermination of the factor employed in the Neumann

method was made. The results obtained are essentially in agreement with those of Heubner, noted above.

"Gregersen's modification [E. S. R., 20, p. 111] to overtitrate the dissolved yellow precipitate with 0.5 normal H_2SO_4 , with a view to remove the carbon dioxid present by boiling, and then titrate back with 0.5 normal NaOH, while in principle correct, is inconvenient, since it increased the time required for each individual analysis. Instead of Gregersen's modification, it is best to run a blank analysis—or, better, several blank analyses—which compensates the errors due (a) to impurities (phosphorus) present in the reagents employed, (b) to carbon dioxid contained in the liquids to be titrated, and (c) to the acidity caused by the action of the boiling standard alkali on the filter paper. The figure secured for the blank analysis is to be subtracted from the acidimetric analysis proper. With uniform work the same blank may be applied to one or even several series of phosphoric-acid estimations."

An extremely delicate colorimetric method for detecting and estimating nitrates and nitrites, E. A. LETTS and FLORENCE W. REA (*Jour. Chem. Soc. [London]*, 105 (1914), No. 618, pp. 1157-1161).—For detecting nitrates and nitrites 0.5 cc. of the solution under examination is mixed with 1.3 cc. of sulphuric acid in a small porcelain crucible, and, after mixing with a glass rod, 0.5 cc. of diphenylbenzidin (0.01 gm. in 50 cc. of sulphuric acid) is added. A blue color indicates either form of oxidized nitrogen. Details for the quantitative determination are given. In the method the depth of color produced is compared with that resulting in a nitrate solution of known strength. When nitrites are in admixture with nitrates it becomes necessary to oxidize the nitrous acid to nitric acid with potassium permanganate.

Fat analysis in fat chemistry in 1913, W. FAHRION (*Ztschr. Angew. Chem.*, 27 (1914), No. 40, Aufsatzteil, pp. 273-290).—An extensive review of the literature on this subject.

Determination of formic and acetic acids, E. HEUSER (*Chem. Ztg.*, 39 (1915), No. 10-11, pp. 57-59, fig. 1).—The usual method of determining formic and acetic acids by acidifying with sulphuric acid and distilling with steam requires too much time for its execution. Furthermore if phosphoric acid is substituted for sulphuric acids the results are influenced, since the former passes over into the distillate. If, however, the vapors are passed through a flask filled with glass beads and heated on a water bath satisfactory results can be obtained.

The method proposed consists of mixing the sample with 50 cc. of water and 50 cc. of phosphoric acid (specific gravity 1.2) and distilling at 44°C . and 56 mm. pressure until a volume of 500 cc. remains in the distillation flask. Then 50 cc. more of water is added to the flask, and distillation is conducted as before. Carbon dioxid is passed through the flask during the distillation. A flask with glass beads is also necessary when acetic acid is being determined in a solution containing both acetic and formic acids. Formic acid is oxidized with potassium dichromate.

The estimation of boric acid in substances, alimentary or otherwise, JAY (*Compt. Rend. Acad. Sci. [Paris]*, 158 (1914), No. 5, pp. 357, 358; *abs. in Jour. Chem. Soc. [London]*, 106 (1914), No. 617, II, p. 217).—A claim for priority over the Bertrand and Agulhon methods. See also work previously noted (E. S. R., 32, p. 206).

Method for the examination of meat extracts, J. SMORODINZEW (*Hoppe-Seyler's Ztschr. Physiol. Chem.*, 92 (1914), No. 2, pp. 214-220; *abs. in Ztschr. Angew. Chem.*, 27 (1914), No. 91, Referatenteil, p. 629).—The highest yield of purins and carnosin was obtained by precipitating with mercuric sulphate. Precipitating with phosphotungstic acid with an addition of sulphuric acid

caused a loss in carnosin, and the use of lead salts involved a decrease in carnitin and had very little effect on increasing the yield of methylguanidin.

The quantitative determination of the amino acids of feeding stuffs by the Van Slyke method, H. S. GRINDLEY ET AL. (*Jour. Amer. Chem. Soc.*, 37 (1915), No. 7, pp. 1778-1781).—The object of this work was to determine quantitatively the amino acid content of feeding stuffs, those used being cotton-seed meal, tankage, and alfalfa hay. Consistently low percentages of amino acid nitrogen were found as compared with the results obtained by Van Slyke (*E. S. R.*, 31, p. 610) with isolated proteins.

"A study is also being made of the free amid and the free amino acids of feeding stuffs, with the object of determining to what extent, if any, the so-called nonprotein nitrogenous substances affect the quantitative determination of the amino acids of feeding stuffs by the Van Slyke method.

"It is evident from the results given that there are marked differences in the amino acid content of the three feeding stuffs here reported. Hence, it is logical to suppose that the feeds would have a widely different nutritive value, particularly as supplements to such feeds as corn.

"The quantitative determination of the amino acids of feeding stuffs, together with the aid of the rapidly increasing evidence on the nutritive functions of the amino acids, will make it possible to extend our present knowledge of feeding stuffs."

Changes in the fat content of feces preserved by freezing without the addition of a preservative, C. A. SMITH, R. J. MILLER, and P. B. HAWK (*Jour. Biol. Chem.*, 21 (1915), No. 2, pp. 395-401).—Analyses of feces before and after freezing at -12° C. it is concluded, show that simple freezing without the addition of a preservative is not applicable to the preservation of feces in which fat is to be determined. The fat of feces kept at a temperature of -12° C. undergoes both hydrolysis (shown by increase in fatty acid) and actual destruction (shown by decrease in total fat).

Food chemistry in the year 1913, J. RÜHLE (*Ztschr. Angew. Chem.*, 27 (1914), No. 92-93, Aufsatzteil, pp. 617-624; 94-95, pp. 625-630).—A retrospect of work done during 1913, dealing with methods of food analysis and the composition of foods.

Tamarind sirup, W. C. TABER (*Jour. Indus. and Engin. Chem.*, 7 (1915), No. 7, pp. 607-609).—The published analyses of tamarinds agree fairly well as to the amount of tartaric acid present. Fruit examined in the Bureau of Chemistry of this Department which was purchased in the New York market had an acidity of 10 per cent calculated as tartaric acid. A large quantity of the acidity was due to tartaric acid and the rest to undetermined acids. No citric acid was found in the sirups made from the fruit.

"The manufacturing process employed in making [true] commercial tamarind sirups consists simply in making a water extract of the tamarinds by adding water to the fruit, heating the mixture for a few hours, filtering it, and adding sugar until a solid content of approximately 60 per cent is obtained. . . .

"The formulas used for making the true tamarind sirup vary somewhat in the amount of fruit used, some manufacturers using as much as 30 to 35 per cent."

The results of an examination (chemical and organoleptic) of six samples of tamarind sirup prepared in the Bureau of Chemistry are given.

Home canning of fruits and vegetables, F. J. CRIDER (*South Carolina Sta. Circ.* 27 (1915), pp. 15).—This publication gives specific directions for home canning of fruits and vegetables by fractional sterilization, open kettle, and steam pressure methods. Canning recipes are included.

Progress made in the chemistry of the fermentation industry in the year 1913, O. MOHR (*Ztschr. Angew. Chem.*, 27 (1914), No. 50, Aufsatzteil, pp. 361-368).—This deals with the chemistry and utilization of the raw materials, fermentation organisms, and processes, and fermented products.

METEOROLOGY.

A study of the radiation of the atmosphere, A. ÅNGSTRÖM (*Smithsn. Misc. Collect.*, 65 (1915), No. 3, pp. V+159, figs. 45).—This report is based upon observations on nocturnal radiation made during expeditions to Algeria and to California. The report is accompanied by records of observations on temperature, pressure, and humidity of the air up to great elevations, made by means of balloon observations from points at or near the observing stations in southern California, as well as of pyrheliometric observations on Mount Whitney.

The more important conclusions reached are that at low altitude (less than 4,500 meters) the total temperature radiation increases with the water-vapor content of the air. An increase in the water-vapor pressure causes a decrease in the effective radiation from the earth to every point of the sky. "The total radiation which would be received from a perfectly dry atmosphere would be about $0.28 \frac{\text{cal.}}{\text{cm}^2 \text{min.}}$ with a temperature of 20° C. at the place of observation.

The radiation of the upper, dry atmosphere would be about 50 per cent of that of a black body at the temperature of the place of observation."

There are indications that the radiation during the daytime is controlled by the same laws that hold for radiation at night. The effect of altitude on radiation is masked by the temperature and humidity gradients of the air. Under normal conditions the effective radiation generally reaches a maximum at an altitude of 3,000 meters, but an increase of the humidity or a decrease of the temperature gradient of the air tend to shift this maximum to higher altitudes. Clouds reduce radiation in dependence upon their altitude and density, while the effect of haze is almost inappreciable when no clouds or real fog are formed.

It is further stated that it is probable that radiation from large water surfaces is almost constant at different temperatures as well as in different latitudes.

The humidity of the air, O. MARR (*Gsndhts. Ingen.*, 38 (1915), Nos. 7, pp. 73-80; 8, pp. 90-93).—This article reports in detail results of studies of the moisture content of the air at different temperatures with constant pressure.

May frosts in Eberswalde and their prediction by means of the psychrometer, J. SCHUBERT (*Ztschr. Forst u. Jagdw.*, 47 (1915), No. 2, pp. 84-92, figs. 4).—Observations on the relation of atmospheric humidity to the formation of frost are reported and discussed.

The influence of volcanic dust veils on climatic variations, H. ARCTOWSKI (*Met. Ztschr.*, 32 (1915), No. 5, pp. 195-199).—A discussion of this subject has already been noted from another source (*E. S. R.*, 32, p. 509).

Ground water level, rainfall, and soil texture, W. KREBS (*Met. Ztschr.*, 32 (1915), No. 1, pp. 44, 45).—As the result of extensive investigations it is thought that the soil moisture content very materially influences the amount of rainfall in a district, and that in intensely cultivated districts the amount of water held by the soil decreases. A permanent drying out of the soil accompanied by the gradual receding of ponds and lakes in a district was found to be accompanied by a gradual decrease in rainfall.

Dew ponds: History, observation, and experiment, E. A. MARTIN (*London: T. Werner Laurie, Ltd.* [1915], pp. 208, pls. 7, figs. 2; rev. in *Amer. Jour. Sci.*,

4. ser., 39 (1915), No. 234, p. 683).—This book embodies the results of previous observations by the author on dew ponds (E. S. R., 25, p. 719; 30, p. 118), as well as of more recent investigations made under the auspices of the Royal Society of England.

The author states that when he commenced his investigations he had a strong leaning in favor of the theory of the replacement of these ponds by dew, but was soon led to abandon this idea, and now believes that, although there is evidence to show that considerable condensation takes place and high-level ponds derive considerable water from condensation of atmospheric moisture other than rain, dew has little or nothing to do with it. He defines a dew pond as "one situated on the higher grounds, generally on the chalkdowns of the south of England, which retains by some means or other a supply of water throughout all but the most prolonged droughts, while those ponds situated on the lower lands have consistently dried up." He explains at length the construction of such ponds and discusses the popular notions in regard to their replenishment. He suggests that the terms mist pond, fog pond, or cloud pond might be more appropriately applied than the term dew pond, since the evidence collected indicates that the condensation of mist furnishes the clue to the perennial nature of these ponds.

The weather element in American climates, R. DE C. WARD (*Ann. Assoc. Amer. Geogr.*, 4 (1914), pp. 3-54, figs. 42).—This is a monographic discussion of this subject under the headings of the weather element in the study of climate, paths of cyclones and anticyclones in the United States, and regional and seasonal weather types of the United States.

The most important paths of cyclones and anticyclones in the United States and their accompanying weather, J. V. HANN (*Met. Ztschr.*, 32 (1915), No. 5, pp. 216-222, figs. 4).—This article is based upon that of Ward noted above.

Climate and meteorology, D. C. BATES (*New Zeal. Off. Yearbook 1914*, pp. 69-90, figs. 6).—This report reviews in some detail the main characteristics of the climate and meteorology of New Zealand, giving summaries of the available data regarding sunshine, temperature, rainfall, and other meteorological factors.

The climate of west Africa, H. HUBERT (*Compt. Rend. Acad. Sci. [Paris]*, 161 (1915), No. 6, pp. 142-144).—The main characteristics of temperature, rainfall, and winds are briefly summarized.

The climate of Abyssinia, Addis Abeba, J. V. HANN (*Met. Ztschr.*, 31 (1914), No. 12, pp. 561-566).—The main characteristics of pressure, temperature, and rainfall are briefly discussed on the basis of the available records.

Meteorological records, L. SMITH (*Rpt. Agr. Expt. Sta. St. Croix, 1913-14*, pp. 38-49, pls. 6).—Tables show the distribution of rainfall at the experiment station of St. Croix during the year ended June 30, 1914, and in different parts of the island in 1913. Temperature, pressure, and humidity records at the experiment station are also given.

Amount and composition of the rainfall at Annas Hope, St. Croix, L. SMITH (*Rpt. Agr. Expt. Sta. St. Croix, 1913-14*, p. 37).—The monthly rainfall and its content of chlorin, total nitrogen, nitrogen as ammonia, and nitrogen as nitrates from July 1, 1913, to June 30, 1914, are reported.

The rainfall régime of Australia, B. C. WALLIS (*Scot. Geogr. Mag.*, 30 (1914), No. 10, pp. 527-532, figs. 2).—The main conclusions of this article are summarized as follows:

"(1) Australian rainfall swings with the sun. (2) The heavy rainfall of the north coast at midsummer is similar in intensity to that of Africa near the tropics of Cancer and Capricorn whenever the sun is vertically overhead. The quantity of the annual rainfall of this section of Australia differs from that of Africa because of the presence of the sea to the north. (3) Australian rain-

fall covers three periods in the year: (a) Mid-December to mid-April, great rainfall intensity in the north becoming less marked in higher latitudes, maximum effect in February; (b) Mid-April to mid-August, winter rains especially in the southwest, maximum in June; (c) Mid-August to mid-December, relative dryness throughout the continent, maximum dryness in November. (4) The heavy summer rains accompanying falling temperatures and the northward swing of the sun. (5) The absence of rain accompanies rising temperatures when the land air is relatively much warmer than the sea air. (6) The heavy winter rains are most intense during the coldest months. (7) The rainfall régime of Australia is essentially similar to that of Africa and is associated with the similarity of air movements south of the equator."

SOILS—FERTILIZERS.

The biochemical decomposition of nitrogenous substances in soils, W. P. KELLEY (*Hawaii Sta. Bul. 39 (1915), pp. 25, fig. 1*).—Ammonification experiments in silica sand and fresh heavy clay soil from a citrus orchard to determine under different conditions the percentage of ammonia derived from the bacterial decomposition of casein, dried blood, soy-bean cake meal, cotton-seed meal, and linseed meal are reported, together with a study of the effects of bacterial action on different groups of nitrogen compounds.

It was found that ammonification of casein in both silica sand and soil was much more rapid during the first two days than that of dried blood, soy-bean cake meal, cotton-seed meal, or linseed meal, while soy-bean cake meal was second in the order of decomposition. A much higher percentage of the total nitrogen in casein was ammonified in soil than of the other materials. When equal amounts of nitrogen were added, casein was still more rapidly ammonified than the other materials and cotton-seed meal and soy-bean cake meal were more completely ammonified than dried blood or linseed meal. Later the yield of ammonia from dried blood exceeded that from cotton-seed meal. Under anaerobic conditions all of the materials were ammonified very slowly during the first two days, after which the casein was converted into ammonia approximately to the same extent as under aerobic conditions, but the other materials were decomposed much less vigorously.

With equal amounts of both nitrogenous and nonnitrogenous matter present the final yields of ammonia from the different materials, with the exception of dried blood, agreed closely, but the initial decomposition of casein was still greater than that of the other substances. By adding 1.586 gm. of starch to 1.072 gm. of casein ammonification was reduced practically 50 per cent throughout nine days, and effects on the ammonification of dried blood were still more marked. With varying amounts of casein the yields of ammonia in four days increased as the amounts of casein present increased. Extending the incubation period beyond four days did not materially increase the yield of ammonia, and the decomposition of the second and third gram added after 1 gm. had been acted upon four and eight days, respectively, was slightly more vigorous than that of the first gram.

Casein when mixed with silica sand or in solution was completely hydrolyzed by the action of bacteria in seven days. In solution the rate of hydrolysis exceeded that of ammonification, but the latter was not so active during the first five days as when mixed with soil.

The determination of the different groups of nitrogen compounds before and after bacterial action in casein, dried blood, soy-bean cake meal, cotton-seed meal, linseed meal, coconut meal, globulin from cotton-seed meal, and zein from maize showed that, with the exception of linseed meal and zein, the basic

diamino acid nitrogen was converted into ammonia more rapidly than the nitrogen of other groups. With casein, soy-bean cake meal, and cotton-seed meal the more rapid ammonification of the basic nitrogen was especially noticeable. These results are taken to indicate that all portions of the organic nitrogen in the different materials used as fertilizers and green manures are not equally susceptible to ammonification.

Further investigations, including a study of the decomposition of individual amino acids and acid amids, are in progress.

The loss of nitrogen and organic matter in cultivated Kansas soils and the effect of this loss on the crop-producing power of the soil, C. O. SWANSON (*Jour. Indus. and Engin. Chem.*, 7 (1915), No. 6, pp. 529-532).—With reference to the average decrease in crop-producing power shown by Kansas soils in spite of improved seeding and tillage methods, data previously reported by the author on the chemical composition of representative Kansas soils (E. S. R., 32, p. 26) are cited to show that the elements nitrogen and carbon have disappeared from the cultivated soils in proportionately larger quantities than the other essential elements. These soils have lost in round numbers from one-fifth to two-fifths of the nitrogen and from nearly one-fourth to one-half of the organic matter. This loss of organic matter and nitrogen is considered to be the most important cause of the decreased crop-producing power of the soils.

Protozoology applied to the soil, N. KOPELOFF, H. C. LINT, and D. A. COLEMAN (*Trans. Amer. Micros. Soc.*, 34 (1915), No. 2, pp. 149-154).—A new method for counting protozoa, consisting of an adaptation of the blood-counting apparatus (Blutkörperzählapparat) whereby the organisms may be counted directly, rapidly, and accurately is described, and experiments to determine the medium best adapted for the large and rapid multiplication of the various kinds of protozoa are reported.

Ten per cent hay infusion proved to be the most favorable medium for the development of large numbers of small flagellates, as well as small and large ciliates. Hay infusion in various concentrations, with and without the addition of egg albumin, was well adapted to the development of the organisms. Hay infusion plus 5 per cent egg albumin proved superior to all other media for the development of ciliates. Soil extract was an excellent medium, though somewhat inferior to hay infusion plus 5 per cent egg albumin, and with the soil used in the experiment lower concentrations than those recommended by Cunningham and Löhnis (E. S. R., 31, p. 26) developed protozoa in a shorter period of time. Three per cent chicken manure was an excellent medium for the development of small ciliates. The general order of appearance of protozoa was as follows: Small flagellates, small ciliates, large flagellates, and finally large ciliates. "The numbers and species of protozoa which can be obtained from a given soil are largely dependent upon the media employed [and] time of incubation, as well as the kind of soil used."

Radio-activity of soils and waters, A. GOCKEL (*Die Radioaktivität von Boden und Quellen. Brunswick: Friedr. Vieweg & Son, 1914, pp. V+108, figs. 10; rev. in Wasser u. Abwasser, 9 (1915), No. 5, p. 135*).—This book summarizes the present knowledge of the radio-activity of soils and waters and contains the following chapters: The radio-activity of the rocks forming the earth's crust, radio-active minerals, the radio-activity of the soil air, soil emanations, the radio-activity of waters, radio-activity and soil heat, and methods of measurement. Methods of procedure in studies of radio-activity are given particular attention throughout the book. It is stated that so far as is now known most soils show radium and thorium emanations. A bibliography is appended.

Studies in the drying of soils, M. A. KLEIN (*Jour. Amer. Soc. Agron.*, 7 (1915), No. 2, pp. 49-77, fig. 1).—In this article the work of others bearing on the subject is reviewed, and two experiments made to determine the effect of drying the soil on its chemical and biological condition and on plant growth are reported.

The object of the first experiment was to determine, under controlled conditions, the effect of drying the soil to different moisture contents on plant food in the soil and on plant growth. Two heavy clay-loam soils, differing only in content of organic matter, were placed in 3-gal. pots, saturated, and then allowed to dry until they reached their permanent moisture content, which varied from 15 to 30 per cent in the soil containing little organic matter and from 15 to 40 per cent in the other, the highest figures indicating saturation. They were then divided into two series, one being planted to wheat at 25 per cent moisture content and the other kept bare at the different moisture contents. The wheat, after being harvested, was followed by millet and buckwheat in turn.

It was found in this experiment that the drying of soil previous to planting had a beneficial effect on plant growth. In the clay loam with little organic matter, which had been previously held at saturation, the yield of dry matter was smallest, while in the clay loam containing considerable organic matter and which had been held at saturation the yield was as large as in those with the lowest moisture content. The factor causing the beneficial effect due to drying is, therefore, considered to be affected by the organic matter in the soil.

Previous drying of the soil had no effect on the total nitrogen in the dry matter of the crop. The water-soluble matter in the clay loam containing little organic matter was increased by drying, while in the same soil with a high content of organic matter the opposite occurred. In the planted series of both soils drying resulted in a decrease in the nitrates in the soil, but no effect was observed in the unplanted series. Denitrification occurred in the soil samples when incubated at 30° C. for seven days. Drying had little effect on the available potassium, calcium, or phosphorus in the soil.

The object of the second experiment was to determine the effect of drying a soil on its physiological condition as measured by carbon dioxid production and nitrification. The clay loam soil was transferred to new pots and kept at an optimum moisture content for 14 months, after which different pots were submitted to from one to three wettings and dryings in a drying room at 30° before determinations of carbon dioxid production and nitrification were made.

It was found that bacterial activity as measured by the carbon dioxid production was greatly increased by a previous drying of the soil. In the soil that was not wet again after drying the bacterial activity was greatly inhibited and the carbon dioxid production ceased after seven days. One drying of the soil greatly increased the activity over the original soil. In the soil kept at an optimum moisture content for 35 days after drying the production of carbon dioxid became normal again. A soil dried twice did not show a much greater activity than when dried once, while three dryings showed no increase over two dryings.

Drying the soil greatly reduced the nitrates, and rewetting of the dry soil for a period of 16 days further decreased nitrification. In the soil held moist for 35 days after one drying and in those previously dried twice and three times, an increase in nitrification was found over that in the sample dried once. The maximum was, however, reached at two dryings. "These results show that the activity of the nitrifying organisms is increased by a previous drying of the soil, but reaches a maximum at two dryings." Adding organic or inorganic

nitrogen to the soil was accompanied by a marked increase in nitrate production.

“From the results obtained in this investigation and by other workers it would seem that the increase in bacterial activity on drying a soil is not a question of bacterial numbers, but depends upon the relative resistance of the important soil organisms. In a consideration of the effect of drying a soil on the physiological condition of the soil no definite conclusions can be drawn until more knowledge is obtained relating to the effect on the different groups of organisms. . . .

“The results of these studies show that the drying of soil affects the physical, chemical, and biological factors, resulting in an increased plant growth. The increased crop growth on a soil that has been previously dried is of importance to the practical question of soil management, more especially in the arid regions where the soil is often air-dried.”

A bibliography of related literature is appended.

A study of the Atterberg plasticity method, C. S. KINNISON (*U. S. Dept. Com., Bur. Standards Technol. Paper 46 (1915), pp. 18, figs. 3*).—In this paper Atterberg's method of measuring the plasticity of clays (*E. S. R.*, 32, p. 617) is briefly described, results obtained by him are reviewed and discussed, and experiments with twenty different clays are reported in which this method of measuring plasticity was compared with some of the present methods.

“Atterberg classifies the condition of a clay with varying amounts of water into five states, as follows: (1) The upper limit of fluidity or the point where the clay slip flows as water; (2) the lower limit of fluidity or flow where two portions of the clay mass can be made to barely flow together, when placed in a shallow dish which is sharply rapped with the hand; (3) the normal consistency, or sticky limit, being the condition in which the clay is most workable, is no longer sticky and will not adhere to metal; (4) the rolling limit, or the condition in which the clay can no longer be rolled into so-called threads between the hand and the surface on which it may rest (this is the lower limit of the workable condition); (5) the condition in which the damp clay will no longer hold together when subjected to pressure.”

The plasticity of 20 different clays was measured by Atterberg's method and their water of plasticity and volume shrinkage determined, together with the amount of water which the dry powdered clay would absorb when allowed to stand over a dilute sulphuric acid solution. Classification according to the Atterberg method and that based on the percentage of water of plasticity were found to agree more closely than those obtained by any two other methods used. The disagreement in the different evaluations was, however, such as to indicate that neither of these methods used alone will suffice, as each produced results which contradict facts observed in every-day experience with the clays. Since Atterberg's rating was nearest the mean, it is considered preferable to either of the ratings based on shrinkage or water of plasticity. It was found further that Atterberg's plasticity number can not be satisfactorily used alone to evaluate clays with reference to their plasticities unless they are all of one type, and will not, therefore, accurately classify a large number of clays of various types.

From these results it is thought that Atterberg's factor should be coordinated with the water of plasticity, this scheme, it is stated, giving promise of separating the nonsticky and safe working clays from the sticky varieties difficult to work.

Soil analysis, E. J. RUSSELL (*Jour. Bd. Agr. [London], 22 (1915), No. 2, pp. 116-119*).—It is pointed out in this article that to derive the maximum assistance from soil analysis the farmer must bear in mind that “the simplest

problem for the expert is to compare soils and, therefore, the chances of success are greatest when a soil survey has been made or when some similar soil has been under proper field experiment. . . . The farmer must . . . arrange to go over the land with the expert and discuss on the spot the various points on which information is desired; the necessary samples can then be drawn with the proper tools and with all due precautions. . . . When no satisfactory standards exist and where the expert has not made a personal inspection, so much balancing of probabilities has to be done that no expert can give more than a general opinion."

Soils of Pennsylvania, F. MENGES (*Penn. Dept. Agr. Buls.* 250 (1914), pp. 11+481, pls. 8; 257 (1914), pp. 285, pls. 8).—This is a popular report on the soils of Pennsylvania, consisting chiefly of a discussion by townships of the origin and capacity of the soils in the State, together with suggestions as to their adaptation to different crops. It was thought advisable to undertake the general survey upon which this report is based because of the great variety and wide diversity of the soil formations of the State and the necessarily limited extent of the surveys made by the Bureau of Soils of this Department.

The soils of the Hawaiian Islands, W. P. KELLEY, W. McGEORGE, and ALICE R. THOMPSON (*Hawaii Sta. Bul.* 40 (1915), pp. 35).—This bulletin discusses briefly the general properties of the soils of the Hawaiian Islands and points out the practical bearings of the investigations (E. S. R., 27, pp. 118, 842; 30, pp. 419, 420; 31, pp. 11, 723; 32, p. 719; 33, p. 122) that have been made on them, especially on the upland soils above the sugar belt.

Hawaii is characterized by a rolling topography, and in almost every section the arable land is broken up by gulches or deep ravines. Owing to the very diverse character of the soils, "the methods of classification and mapping usually employed in soil surveys are not adapted to Hawaiian conditions, and nothing less than a systematic sampling of almost every acre will suffice to give an accurate idea of the location of all soil types."

The soils are lateritic in nature, range from 6 in. to many feet in depth, and, with the exception of small areas near the sea, have been formed from the disintegration products of basaltic lava. They are, therefore, highly ferruginous and basic. Unusual types of soil also occur on the islands, there being on Oahu highly manganiferous and titaniferous soils. Much of the soil at lower elevations has been formed by sedimentation and erosion from higher elevations. "After a few years of cultivation, but little demarcation between the soil and the subsoil is left except in locations of heavy rainfall. The humus content in passing downward decreases slowly, but the fertility in the drier sections is not greatly different for many feet below the surface. . . . No injurious effects, such as commonly follow the turning up of inert subsoil, are produced in the drier sections by plowing to the depth of 30 in."

The soils, in general, are divided, as regards mechanical composition, into clay, silt, sandy, and humus soils, the clay type predominating. The predominant color is red. "The potash content, on the whole, is rather below the average, but frequently it is relatively more soluble than usual and consequently more available. It is also more constant in different sections of the islands than any other of the so-called plant-food constituents. Phosphoric acid is comparatively abundant, but there is a wide range of variation in the percentages present. . . . Notwithstanding the high percentages of phosphoric acid in Hawaiian soils, the availability is, on the whole, rather low, and phosphate fertilization is necessary in most instances except where the humus content is high. . . . The humus content is high as compared with mainland soils, and consequently the nitrogen is also high, but its availability is low, due to poor aeration. . . . Notwithstanding the highly basic character of Hawaiian soils, they generally give

an acid reaction toward litmus. . . . The amount of water-soluble ferrous iron . . . is extremely small, except where there is insufficient aeration. . . . In general the aeration of Hawaiian soils is not sufficient for the best development of beneficial bacteria. . . . The results of experiments indicate that the iron and alumina present may partially take the place of lime in maintaining the necessary neutral condition. On the other hand, experiments show that magnesium carbonate seems to be distinctly detrimental to nitrification, while the magnesia naturally present in the soils does not seem to interfere. . . . Ammonification is more active in Hawaiian soils than nitrification, and investigations show that aeration is not as essential to this process as it is to nitrification."

Proper drainage, frequent deep plowing, and proper rotation of crops to maintain the humus supply are considered to be essential in the proper management of the soils. The application of lime for the improvement of heavy clays has been of doubtful effect. "With the exception of phosphoric acid, all the mineral elements of plant food in Hawaiian soils are soluble in water to a considerable extent, and if suitable physical conditions be maintained, and the humus content kept up, the need for mineral fertilizers will be greatly reduced. The solubility of the mineral constituents can also be considerably increased by soil heating."

Tables of mechanical and chemical analyses of a large number of soils and subsoils taken from different parts of all of the principal islands are also given.

Van Bemmelen's method in the study of lateritic soils and the process of laterization in Italian soils, A. DE DOMINICIS (*Staz. Sper. Agr. Ital.*, 47 (1914), No. 4, pp. 282-296; *abs. in Chem. Abs.*, 9 (1915), No. 5, pp. 680, 681).—The work of others bearing on the subject is briefly reviewed, and experiments with soils from northern and southern Italy, using van Bemmelen's method for studying lateritic soils, are reported, from which it is concluded that even though van Bemmelen's method gives no quantitative results it does give information regarding the nature of the soil colloids. Of the two classes of colloids, the first includes those soluble in hydrochloric acid in which the ratio of alumina to silica is not less than 1:3, and the second class consists of compounds of alumina and silica in the ratio of less than 1:3 and which are soluble only in sulphuric acid.

The results of these studies appear to be in accord with those of Barnardini and Mazzone (*E. S. R.*, 30, p. 320) with reference to the lateritic nature of the soils of southern Italy.

Soils, H. J. VIBOND (*Union So. Africa Dept. Agr. Rpt. 1913-14*, pp. 218-230, pls. 10).—Chemical and mechanical analyses of various types of Transvaal soils are reported and discussed.

Chemical analyses of a number of soils and subsoils from the different forest stations showed them to be of five classes, namely, soils with good percentages of nitrogen, soils well supplied with lime, heavy soils, medium to sandy loams, and sandy soils. There appeared to be a regular decrease in the percentages of lime, magnesia, potash, and phosphoric acid soluble in strong hydrochloric acid as the soils varied from heavy to light. There was, however, little difference between the heavy and light soils with reference to available phosphoric acid and potash. "All five groups appear to contain adequate amounts of available potash for cereal production, but very inadequate amounts of available phosphates," while the heavy soils, medium to sandy loams, and sandy soils "also appear to be deficient in nitrogen and are certainly deficient in lime."

Mechanical and chemical analyses of a number of soils belonging to six typical groups, namely, (1) black turf soils, (2) red and brown heavy loams or clay loams, (3) gray and brownish gray heavy loams to clay loams, (4) red

and brown medium to sandy loams, (5) gray and brownish gray medium to sandy loams, and (6) sandy soils and a number of miscellaneous soils, are also reported.

"One feature of these soils is their poverty in the silt, fine silt, and very fine silt fractions. In this respect the typical gray soils are better supplied than the typical red sedentary soils, but even they show comparatively small percentages of the finer silts. The gray soils also contain less fine gravel and 'sand' and more 'fine sand' than the corresponding red and brown soils."

The important cementing material of the soils was found to be iron oxid. Data on the relation between the color of soils and their iron oxid content indicate that "the gray soils are very much poorer in iron oxid than the red and brown soils, and the brown soils are as a rule poorer than the red soils except where the humus content is high. The brown in any case is to be regarded as a mixture of red due to iron oxid, and black due to humus. The percentages of iron oxid in the clay fraction would probably be a better guide, as the iron oxid locked up in the ironstone grains (which are abundant in many soils) can not have much coloring effect."

Studies of two soils showed that in one case a third and in the other case a quarter of the total phosphoric oxid in the soil was locked up in the ironstone grain.

Experimental data on podzol formation, V. P. SMIRNOV (*Ezheg. Geol. i Min. Rossiï, 14 (1912), No. 7-8, pp. 206-210, fig. 1; abs. in Zhur. Opytn. Agron. (Russ. Jour. Expt. Landw.), 15 (1914), No. 3, pp. 228, 229.*)—In experiments with a sandy podzol soil two glass tubes 5 cm. in diameter were filled with the soil in its natural stratification, and distilled water, distilled water containing carbon dioxid, and a solution of ammonia were allowed to percolate through the soil for twenty-four hours. The filtrates contained different amounts of leached-out organic and inorganic constituents, the smallest amount being in the distilled water containing carbon dioxid and the most in the ammonia solution.

These results, together with preliminary analyses of the soil layers, led to the conclusion that the cementing material of the subhorizons of podzol soil consists of organic matter and colloidal silica. In the tube treated with ammonia a brown ring appeared between the lower subhorizon and the subsoil, which is thought to be an ortstein formation.

The question of the formation of secondary minerals in the ortstein-producing horizons of soils, B. B. POLYNOV (*Ezheg. Geol. i Min. Rossiï, 14 (1912), No. 9, pp. 273-280; abs. in Zhur. Opytn. Agron. (Russ. Jour. Expt. Landw.), 15 (1914), No. 3, p. 228.*)—A brief morphological description and mechanical and chemical analyses of each layer of two podzol soils are reported, together with experiments on the absorptive power of each layer for ammonia.

A marked increase in absorptive power and in amount of sesquioxids, chemically combined water, alkaline earths, potassium, and mechanical clay (less than 0.01 mm.) was observed in the ortstein-producing subhorizons as compared with the upper horizons. The increase in absorptive power for ammonia is attributed to the presence in the ortstein-producing layers of "secondary soil minerals," such as the colloidal hydrates of silica and ferric oxid, which have a high absorptive power for ammonia, and also to accumulations in these layers of zeolite-like secondary hydrous aluminum silicates of magnesium, potassium, and calcium.

Alkali or kalar experiments and completion report of the Daulatpur reclamation station, Sind, G. S. HENDERSON (*Dept. Agr. Bombay Bul. 64 (1914), pp. 34, pls. 6, figs. 2.*)—In this report experience in the United States and in

Egypt on the reclamation of alkali land is briefly reviewed, soil conditions with reference to alkali in the province of Sind are described, and reclamation experiments extending from 1908 to 1913, inclusive, on 400 acres of loam to sandy loam soil which was typical of the worst areas of kalar (alkali) land in Sind are reported.

It is stated that the alkali problem in Sind is not a difficult one. "None of the lands so far examined in use for agricultural purposes contain very high percentages of alkali, but a number of these contain just sufficient kalar to have an injurious effect on the yields of the crops." The reclamation experiments included leveling, flooding, and draining of the land, and cropping to berseem (Egyptian white clover), sorghum, and cotton.

Considering the cost of reclamation and the crop returns, it is stated that the experimental farm has not paid. The berseem demonstrated its fitness as a rotation crop for the country.

Methods of reclamation, including flooding and cropping to rice and white clover, based mainly on the ability of these crops to withstand large amounts of water, are discussed.

Technical means of improving alkali soils, L. KIRILLOV (*Khoz'jaistvo*, No. 26 (1913); *abs. in Zhur. Opytn. Agron. (Russ. Jour. Expt. Landw.)*, 15 (1914), No. 2, p. 147).—For the improvement of alkali soils the author recommends shallow plowing (1.75 to 3.5 in.) in the fall, followed immediately by deepening the soil an inch more. For the winter the soil is to be covered by old manure which is plowed under in the spring. The sowing must be early and preferably of broad-leaved plants in rows so that a cultivator can pass through later. It is thought that the effect of such treatment will last for from three to four years, permitting the growth of perennial grasses, like alfalfa, for from four to five years, after which the treatment should be repeated.

The transformation of sulphur and sulphur compounds in agricultural soil, a contribution to the knowledge of the sulphur cycle, H. KAPPEN and E. QUENSELL (*Landw. Vers. Stat.*, 86 (1915), No. 1-2, pp. 1-34).—The authors review briefly the work of others bearing on the subject and report experiments on the transformations undergone by sulphids, free sulphur, and sulphites in different soils.

It is concluded from these experiments that hydrogen sulphid produced in soils by bacterial action or rotting of organic compounds passes into the form of ferrous sulphid which is decomposed in the soil air, the iron being oxidized to iron oxid and the sulphur being set free. The free sulphur in finely divided condition is then oxidized into sulphites and these into sulphates. The speed of this transformation of free sulphur into sulphates was found to be dependent on the form of sulphur used, the so-called milk of sulphur being the easiest form oxidized. Oxidation of free sulphur took place more quickly in natural than in sterilized soil. This is taken to indicate that bacteria may aid in the transformation of sulphur compounds in soil, although it is thought that the process is mainly a chemical one since all known methods of soil sterilization are considered to have an effect on the other soil properties.

It is further concluded that the transformation of sulphur compounds takes place much more rapidly in soils than elsewhere and that different soils exert specific influences on the speed of such transformation. It was also found that sulphids and sulphites are transformed so rapidly in soils that the germination or development of plants is not injuriously affected.

Rich harvests on poor sand soil, A. KOCH (*Mitt. Deut. Landw. Gesell.*, 30 (1915), No. 21, pp. 311-315, figs. 5).—Pot experiments with clean sand and a mixture of clean sand and clay, both of which were completely fertilized and planted to corn, wheat, rye, oats, and buckwheat are reported, the purpose of

which was to determine the influences of the physical properties of soil on the yield of crops.

The crops grew much faster and the yields were considerably greater on the sand clay mixture than on the sand. With corn the best results were obtained with a mixture of 5.4 kg. of sand and 0.9 kg. of clay. The wheat, rye, oats, and buckwheat yield on the sand-clay mixture were as large as in good loam soil. When sand was treated with nitric acid and water allowed to percolate through nearly all the nitric acid was washed out, while the sand-clay mixture under the same circumstances retained a large part of the nitric acid.

Experiments to explain the greater crop-producing power of the sand-clay mixture on the basis of greater absorptive power for plant food, greater moisture-retaining power, and greater capillarity were unsuccessful. Studies of the root development of the crops and physical experiments with the two soils led to the conclusion that the sand grains when wet offer considerable resistance to the growth and spreading of plant roots, while when mixed with clay the clay acts as a lubricant between the sand grains, thus permitting roots to spread throughout the mixture, making a greater feeding area, and resulting in larger crop yields.

It is concluded from the results as a whole that the physical condition of a soil determines in large measure the availability and extent of utilization of plant food by plants and, therefore, exercises considerable influence on the yield of crops.

Unfavorable influence of too close a stand of trees on the water economy of poor pine soils, ALBERT (*Ztschr. Forst u. Jagdw.*, 47 (1915), No. 4, pp. 241-248, figs. 2).—Investigations on the effect of thinning out the stand of pine trees on the moisture content of light sand soil of relatively low fertility are reported.

A pine tree thicket 20 to 25 years old was divided into three plats. The number of trees on two of the plats was reduced and the resulting brushwood removed from one and allowed to remain on the other. Soil moisture observations made during two growing seasons thereafter showed that in the soil of the thinned-out plats there was a noticeable and permanent increase in the moisture content. The increase was greater for the plat on which the brushwood covering was allowed to remain. This is attributed to the decrease in evaporation caused by the covering. It is also thought that the brush increased the fertility of the soil.

It is concluded that a proper thinning-out of pine tree growths on poor sand soils, but allowing the brush to remain, is beneficial not only to the trees but to the soil.

A note on relative saturation, G. BROWN (*Jour. Ecology*, 3 (1915), No. 1, pp. 30, 31).—The author discusses and proposes as a general expression for the condition of a soil with regard to its relative saturation, the formula $(w-m)/W$, in which w = the mass of a given quantity of soil with its contained moisture, m = the mass of same soil when air dry, and W the maximum water capacity, all being expressed in grams.

For each natural habitat there will be a minimum, an optimum, and a maximum value of the ratio, the optimum indicating those edaphic conditions under which the association or formation remains stable, the maximum and minimum indicating the limiting conditions beyond which it can no longer be maintained as such, but will be replaced by a drier or wetter type. Relative saturation as here indicated would, it is claimed, prove an efficient measure of the soil water without taking into consideration the physical condition of the soil, and would serve to differentiate edaphic conditions and to distinguish natural habitats.

Pot tests with fertilizers compared with field trials, G. N. COFFEY and H. F. TUTTLE (*Jour. Amer. Soc. Agron.*, 7 (1915), No. 3, pp. 129-139, fig. 1).—Pot fertilizer experiments with wheat on different soil types are reported, the purpose of which was to determine the value of pot tests for indicating the fertilizer requirements of a given soil.

The pot tests were made with soils as similar as possible to those upon which field trials are being conducted and the results compared with those secured in the field, the idea being to duplicate field conditions and fertilizer treatments as nearly as possible. Five-gallon glazed clay pots about 10½ in. in diameter and 12 in. deep were used. The surface soil and the first 6 in. of subsoil from different fields were used, and equal weights (about 10 kg.) of both soil and subsoil were used in each pot. It was found that the results of pot tests and field trials made as indicated agreed on the whole very closely.

Data on the experience with fertilizer pot tests at other experiment stations were also obtained, the consensus of opinion of those reporting success being that if one element is needed the pot test is quite reliable in indicating it, while if two or more elements are lacking the pots may differ from field indications.

It is concluded from the results of these experiments and the experience of other stations that pot tests may be made of very great value in determining the relative need of the soil for different plant food elements. To secure the best results the soil should be placed in the pots in as nearly the same position and condition as in the field and receive the same fertilizer treatment as in field practice. "Both soil and subsoil should be used, the surface soil being taken to the depth at which the most marked change takes place, usually about the depth to which it is plowed. Air drying and excessive handling should be avoided. . . .

"A somewhat larger quantity of seed per acre should be sown and the plants thinned to about the same number per acre as in the field and to an equal number per pot. While most stations have grown the plants to maturity, the results secured here seem to show that with wheat a period of one month to six weeks is sufficient to indicate the relative fertilizer need of the soils studied. The dry weight is considered most reliable. The tests should be made in not less than triplicates and statistical methods should be applied."

General notes on manures, their value and use, J. S. J. McCALL (*Nyasaland Dept. Agr. [Pub.]*, 2 (1915), pp. 8).—General information on the subject, including brief instructions as to the purchase of fertilizers, is given with particular reference to the tobacco-raising localities of Nyasaland.

Illustration of important properties of peat litter, G. KEPPELER (*Mitt. Ver. Förđ. Moorkultur Deut. Reiche*, 33 (1915), No. 3, pp. 41-44, pls. 2).—Comparative experiments on the properties of peat litter and straw with reference to their values when used in stable manure are reported.

It was found that 300 gm. of peat litter absorbed 4,500 gm. of water as against 800 gm. of water absorbed by 300 gm. of straw. Two gm. of peat litter absorbed approximately 1 liter of ammonia in the same time that 2 gm. of straw absorbed only 0.2 liter of ammonia. It was also found that pulverized straw molded much more quickly than pulverized peat with the same content of water and nutritive solution.

These results are taken to indicate that peat litter is much more valuable than straw for use in stable manure, inasmuch as its superior absorptive power for water and ammonia and its inhibitive action toward bacterial decomposition will prevent the loss of ammonia from animal excrement.

Investigations on the absorptive power of peat dust for water, H. MINNSEN (*Mitt. Ver. Förđ. Moorkultur Deut. Reiche*, 33 (1915), No. 3, pp. 44-52).—Experiments with eight samples of four different kinds of peat are reported, the

purpose of which was to determine their absorptive powers for water when pulverized to the following different degrees of fineness: Ten to 20 mm., 4 to 6 mm., 3 to 4 mm., 2 to 3 mm., 1 to 2 mm., 0.4 to 1 mm., 0.2 to 0.4 mm., 0.1 to 0.2 mm., and less than 0.1 mm.

From the results obtained, the peat dust made from pure kinds of peat having grains 0.2 to 2 mm. in diameter is considered to have on the average the greatest absorptive power for water.

Peat litter and nitrogen deficiency, W. BERSCH (*Ztschr. Moorkultur u. Torfverwert.*, 13 (1915), No. 1, pp. 33-38).—Data from various sources are reviewed which, taken as a whole, indicate that peat litter, owing to its greater absorptive power, when used in the handling of animal excrement permits less loss of nitrogen by leaching and evaporation than straw litter and produces a stable manure much richer in available nitrogen.

The influence of lime nitrogen on the germination of barley and wheat, R. TENKA and B. MYSIK (*Ztschr. Landw. Versuchsw. Österr.*, 18 (1915), No. 3, pp. 58-63).—Experiments with a sandy loam soil well stocked with humus and plant food to determine the effect of additions of 200, 600, and 1,200 kg. per hectare (178, 534, and 1,068 lbs. per acre) of lime nitrogen on the germination of wheat and barley, when planted at the same time as and 4, 8, 13, 17, and 26 days after treatment with lime nitrogen, are reported.

The smallest addition of lime nitrogen retarded the germination of wheat and barley planted at the time of treatment. The retardation with wheat was, however, greater than with barley. The medium application of lime nitrogen retarded the germination of both wheat and barley planted at the same time as and 4 days after treatment, but the recovery of the barley was rapid while the wheat recovered more gradually. With the largest lime nitrogen addition the barley planted at the time of treatment and 4 days later was retarded strongly, and the effect was noticeable in barley planted 8 days later. The recovery was also very gradual. The germination of wheat planted at the time of treatment and 4 days later was almost completely inhibited, no germination taking place until after the seventh day in the second case. In wheat planted 8 days after treatment only slightly unfavorable effects were noticeable. The transformation of the lime nitrogen into urea, ammonia, and nitric acid occurred very rapidly.

The action of the nitrogen of a new molasses-sludge fertilizer, T. PFEIFFER and W. SIMMERMACHER (*Fühling's Landw. Ztg.*, 64 (1915), No. 7-8, pp. 177-187).—The work of others on the fertilizing value of molasses sludge in different combinations is briefly reviewed, and pot experiments with oats and mustard on a sand soil mixed with loam, comparing ammonium sulphate and a so-called superphosphate molasses sludge fertilizer as sources of nitrogen, are reported. This fertilizer contained 1.87 per cent total nitrogen, 0.08 per cent ammonia nitrogen, 9.21 per cent water-soluble phosphoric acid, and 4.44 per cent potash. Sufficient superphosphate was added with the ammonium sulphate to place the ammonium sulphate pots on the same basis as the molasses sludge pots with reference to phosphoric acid.

Greater yields of oats were obtained with the ammonium sulphate than with the molasses-sludge fertilizer, but in both cases the increase in yield decreased as the nitrogen additions increased. This result is attributed in both cases to the presence of an excess of phosphoric acid, it being found that in pots receiving no nitrogen fertilization the yield of dry matter was greater with low than with high phosphoric acid fertilization.

After harvesting the oats, mustard was planted in the pots to determine the after effect of the two fertilizers. It was found that the molasses-sludge fertilizer had a better after effect than the ammonium sulphate. The increase in the

combined yields of oats and mustard increased in amount as the nitrogen additions increased. It is thought, therefore, that at least in the case of the molasses fertilizer the excess of phosphoric acid favored the utilization of the nitrogen by the plants.

In consideration of these results and of those obtained by others it is concluded that the molasses-sludge fertilizer is from 53 to 74 per cent as effective as ammonium sulphate as a source of nitrogen for plants.

The production of phosphate rock in 1914. W. C. PHALEN (*U. S. Geol. Survey, Mineral Resources of the United States Calendar Year 1914*, pt. 2, pp. 41-56).—This report deals with the production, sale, and use of phosphate rock in different States, and with imports and exports of fertilizer materials during 1914.

The marketed production of phosphate rock in the United States in 1914 was 2,734,043 long tons, which represents a decrease of 12 per cent in quantity and 19 per cent in value compared with the production in 1913, and a decrease of 7 per cent in quantity and 17 per cent in value as compared with the average annual production of the 4-year period prior to 1914. The quantity of phosphate rock mined in 1914 was 2,649,174 long tons, or nearly 16 per cent less than that mined in 1913. In Florida the decrease amounted to nearly 19 per cent, in Tennessee 3 per cent, in South Carolina 1.4 per cent, and in the Western States 13 per cent.

There was reported to the Survey in 1914, 48,317 long tons of phosphate rock as having been sold in finely ground form for direct application to the soil. During 1914, 964,114 long tons of phosphate rock were exported from the United States, mainly from Florida, which represents a decrease of 402,394 long tons as compared with the export in 1913.

The phosphate industry in the Southern and Western States and in foreign countries is briefly discussed.

Potash production in California. T. H. NORRIS (*U. S. Dept. Com., Com. Rpts., No. 137 (1915), pp. 1166-1169*).—This report states that attempts to develop a domestic potash industry are more advanced in California than in any other section. The most promising mineral source of potash is thought to be the saline deposits at Searles Lake in San Bernardino County. It is also stated that experiments have indicated the technical feasibility of extracting sulphate of potash from Utah alunite, but the utilization of the enormous masses of seaweed growing off the Pacific coast is considered to offer better chances of solving the potash problem. Data as to the supply, composition, harvesting, preparation, direct use, and extraction of the potash of kelp are given. The author is of the opinion that any extended successful development of the industrial extraction of potash salts from the kelp beds "would ultimately place this country in a position to cover not only the large domestic demand for these compounds, but to meet German competition in other lands, more especially in supplying the wants of countries on the Pacific."

The waste from sawmills as a source of potash. C. T. GIMMINGHAM (*Jour. Bd. Agr. [London], 22 (1915), No. 2, pp. 146-148*).—Attention is drawn to the possibility of utilizing wood ashes and flue dust obtained from sawmill furnaces in place of kainit when potash manuring is contemplated by farmers and timber merchants in the neighborhood of sawmills. Analyses of wood ash and flue dust showed that the latter is the more valuable, sometimes containing as high as 10 per cent of potash and having about the same fertilizing value as kainit.

Cultivation of seaweed in Ireland. G. H. PETHYBRIDGE (*Dept. Agr. and Tech. Instr. Ireland Jour., 15 (1915), No. 3, pp. 546-549, pls. 5*).—It is pointed out in this article that the varieties of seaweed useful as potash manure all grow attached to rocks or stones, and consequently these weeds are absent from those

portions of the coast where such rocks and stones are not present; that is, in sandy or muddy bays or estuaries. The process of so-called cultivation here described consists in providing suitable anchorage, generally large stones, between the tide marks in such localities, upon which the seaweed may be made to grow.

Experiments with a kieselguhr-sulphite fertilizer, L. KERN (*Papier Ztg.*, 40 (1915), No. 10, pp. 194-196; *abs. in Chem. Abs.*, 9 (1915), No. 8, p. 1086).—A mixture consisting of equal parts of waste sulphite liquor from chemical pulp mills and impure kieselguhr, containing appreciable amounts of soluble potash, phosphates of lime, and soluble silica, was found to be easy to distribute and to be of considerable fertilizing value.

Experiments with hay crops showed that the sulphurous acid of the waste liquor had passed into harmless compounds. An analysis of a sample of the mixture gave the following results: Loss on ignition, 36.74 per cent; nitrogen, 0.15; total sulphates, 4.04; silica soluble in hot hydrochloric acid, 0.099; silica soluble in caustic soda solution, 33.39; iron and alumina, 1.33; lime, 4.43; magnesia, 0.15; phosphoric acid, 0.99; and potash, 0.48 per cent. The value of this mixture as a fertilizer is attributed largely to its considerable content of soluble silica. The organic matter present in the mixture also appeared to be beneficial in soils deficient in humus and furnished a favorable medium for bacterial growth.

Agricultural lime analyses (*Id. Agr. Col. Quart.*, No. 68 (1915), pp. 11).—Actual and guaranteed chemical analyses of 133 samples of agricultural lime offered for sale in Maryland during the period from June, 1914, to May, 1915, and mechanical analyses of 16 samples of ground limestone and ground oyster shell are reported, together with a brief statement on the use of lime. The text of the Maryland lime-inspection law is also given. A warning is given against the purchase of so-called stone-meal fertilizer, which, it is stated, contains approximately only 20 per cent of calcium and magnesium oxids and no soluble potash or phosphoric acid.

Favorable action of manganese on the bacteria of leguminous plants, M. D. OLARU (*Compt. Rend. Acad. Sci. [Paris]*, 160 (1915), No. 8, pp. 280-283; *abs. in Chem. Abs.*, 9 (1915), No. 11, p. 1525).—Experiments on the effect of manganese on the nitrogen-fixing bacteria from the root nodules of leguminous plants are reported.

Manganese sulphate was added to a nutritive medium (containing 2 per cent sucrose), in which the bacteria were cultivated, in amounts varying from 1 part per 10,000,000 to 1 part per 100,000. After incubating at 19° C. for 48 hours, it was found that the maximum increase in nitrogen was obtained when the manganese was present in the strength of 1 part per 200,000 of nutritive medium. Two other experiments with a slightly weaker nutritive medium which contained less initial nitrogen, extending over 50 and 114 days, showed that the optimum quantity of manganese was 1 part per 50,000 of nutritive medium in each case. The nitrogen increases in the presence of manganese were in all cases considerably greater than in the controls.

From these results the use of manganese as a fertilizer is thought to be important from the standpoint of the bacterial fixation of nitrogen.

Mussels as manure (*Jour. Bd. Agr. [London]*, 22 (1915), No. 2, pp. 156, 157).—From an inquiry made by the Board of Agriculture of England into the manurial value of mussels it was found that in some cases "mussels would have a certain manurial value. The whole mussel (shell and contents) would seem to contain from 0.7 to 1 per cent of nitrogen, 0.14 to 0.54 per cent of phosphate, and from 0.09 to 0.13 per cent of potash." The mussel shells con-

sist almost wholly of carbonate of lime. To obtain the best results it is considered advisable to crush or grind the mussels and mix them with the soil.

Soot as manure (*Jour. Bd. Agr. [London]*, 21 (1915), No. 11, pp. 1043-1046; *abs. in Mark Lane Express*, 113 (1915), No. 4353, p. 261; *Jour. Soc. Chem. Indus.*, 34 (1915), No. 7, p. 369; *Chem. Abs.*, 9 (1915), No. 12, pp. 1651, 1652).—The composition, fertilizing value, and use of soot on different crops are briefly discussed.

It is shown that soot is very variable in weight and composition. Domestic soot is usually the richest and may contain from 3 to 6 per cent of nitrogen. The lighter the soot the higher the percentage of nitrogen. The weight per bushel varies from 9 to 33 lbs., and a good soot should not weigh more than 28 lbs. per bushel. The average soot from dwelling houses was found to contain about 1 lb. of nitrogen per bushel. Soot is especially recommended for the top-dressing of wheat and other grain in early spring. It is usually applied at the rate of about 20 bu. per acre. It is most easily handled and gives the best results if mixed with loam and superphosphate and potash salts before application.

Analysis of the flue dust from iron works is reported showing phosphoric acid 0.96 per cent, potash 5.92, and lime 7.28. It is stated that there are large quantities of this material which might be profitably used as a fertilizer.

Analyses of fertilizers—fall season, 1914, B. W. KILGORE ET AL. (*Bul. N. C. Dept. Agr.*, 36 (1915), No. 4, pp. 92).—Actual and guaranteed analyses of 264 samples of fertilizers and fertilizing materials offered for sale in North Carolina during 1914 are reported which show that their composition is, as in previous years, in general about as guaranteed. Brands of fertilizers registered for the season 1914-15 are also reported with their guaranties.

Commercial fertilizers, W. B. CADY (*Porto Rico Bd. Agr. Expt. Sta. Bul.* 13 (1915), pp. 15; *Spanish Ed.*, pp. 13).—This bulletin contains actual and guaranteed analyses of 91 samples of fertilizers and fertilizing materials for sale in Porto Rico in 1914 and of 13 samples of guano and 3 samples of wood ashes. Of the fertilizers analyzed 23 were found to be deficient in one or more constituents. The phosphoric acid content was equal to the guaranty in all but 4 samples and in many samples exceeded the guaranty. The guanos analyzed contained sufficient fertilizer material (0.3 to 8.40 per cent of nitrogen, 2.54 to 37.18 per cent of phosphoric acid, and from none to 3.7 per cent of potash) to be considered worth exploiting.

A short note on the purchasing of fertilizers and the text of the law regulating the registration and inspection of fertilizers and fertilizing materials are also given.

Analysis of fertilizers by the Virginia Department of Agriculture for 1915 (*Dept. Agr. and Immigr. Va. Bul.* 100 (1915), pp. 13-25).—Actual and guaranteed analyses and valuations of 213 samples of commercial fertilizers and fertilizing materials offered for sale in Virginia in 1915 are reported. According to the actual analyses, of the total number of samples examined, about 8 fell below the guaranty in composition.

[**Fertilizer analyses**], H. J. VIBOND (*Union So. Africa Dept. Agr. Rpt.* 1913-14, pp. 230-233).—Analyses of bat guano, commercial fertilizers received from manufacturers and farmers, kraal manure, and limes and limestones are reported. The quality from the agricultural standpoint of limestones available in Transvaal is discussed.

Statistics of the commercial fertilizer industry in Austria-Hungary, F. W. DAFERT and R. MIKLAUZ (*Ztschr. Landw. Versuchsw. Österr.*, 18 (1915), No. 1-2, pp. 1-10).—Statistical data on the production, sale, use, exports, and

imports of superphosphate, Thomas slag, sodium nitrate, ammonium sulphate, and potash salts in Austria-Hungary for the year 1907 to 1912, inclusive, are reported.

AGRICULTURAL BOTANY.

Studies on variation and selection, A. L. and Mrs. A. C. HAGEDOORN (*Ztschr. Induktive Abstam. u. Vererbungslehre*, 11 (1914), No. 3, pp. 145-183, figs. 4; *abs. in Internat. Inst. Agr. [Rome], Mo. Bul. Agr. Intel. and Plant Diseases*, 5 (1914), No. 4, p. 477).—This is a survey of the progress that has been made in the Mendelian interpretation of variation and selection. The difficulties of the present terminology are pointed out and a plea is made for a more precise definition and use of terms. Some criticisms by zoologists are discussed in connection with facts previously cited by the authors (*E. S. R.*, 31, p. 130), who claim that genes can not be modified by any selection.

Graphic representation of Mendelian inheritance, P. WAGNER (*Jahresber. Ver. Angew. Bot.*, 11 (1913), No. 2, pp. 137-141, fig. 1).—A device is described which is intended to present concretely to students of heredity and breeders the manner and practical results of the combination, in breeding practice, of one, two, or three pairs of characters as carried through several generations. Examples of the results obtained from its use are discussed.

Inheritance of the capacity for production, T. ROEMER (*Fühling's Landw. Ztg.*, 63 (1914), No. 8, pp. 257-268; *abs. in Internat. Inst. Agr. [Rome], Mo. Bul. Agr. Intel. and Plant Diseases*, 5 (1914), No. 8, pp. 1010, 1011).—Investigations cited are held to show that there is no essential difference as regards mode of inheritance between morphological and biological characters. But since biological characters are apparently the expression of a number of units, the investigation of the Mendelian inheritance of capacity for production is very difficult on account of the numerous slight variations arising in the second generation. Although (on account of the difficulty or impossibility of analyzing the hybrids according to their capacity for production) agricultural breeding work can not utilize Mendelian laws with as much certainty and fullness as can some branches of horticultural work, it is held that in the crossing of two races all the possible combinations of the unit characters borne by each will appear, that the further possibilities of crossing will become evident, and that the only true test of hereditary disposition and hence of breeding value in a strain is not its outward appearance but its actual progeny.

These points hold for all types of breeding, and the possibility of obtaining thereby forms more productive or otherwise more valuable than either parent is regarded as highly important. It obviates the necessity of using individuals having extreme development in greatly desired lines, perhaps combined with deficiency in less desirable ones, so that by the third generation the breeder may reach a definite result without any fear of valuable material having been unwittingly discarded.

Morphology as a factor in determining relationships, J. M. GREENMAN (*Amer. Jour. Bot.*, 2 (1915), No. 3, pp. 111-115).—Discussing some investigations and views on morphology and relationship as recently published, the author calls attention to the necessity for cooperation by the larger botanical institutions throughout the world. This is held to be an essential condition for the numerous specialized and intensive studies necessary to development of the life histories of plants and other exact and detailed study of problems bearing upon the main phases of phylogeny and the chief lines of evolution of the higher plants.

The experimental study of genetic relationships, H. H. BARTLETT (*Amer. Jour. Bot.*, 2 (1915), No. 3, pp. 132-155).—The author holds that the immediate

aims of the geneticist are (1) to observe the origin of new and distinct forms, the genetic relationship of which must, therefore, be known, (2) to determine the conditions which brought these forms about, so as to be able to produce them at will, and (3) to study their hereditary behavior and their morphological and chemical characteristics in order to provide a basis for sound deduction in regard to the genetic relationships of organisms. All of these aims are declared to have been realized in some measure as a result of the recent activity in the study of genetics. This view is upheld in a synthetic discussion of the work and opinions of various authors.

Subdivisions should extend as far as any one finds necessary, since the geneticist needs to have definite designations for much smaller groups than the ecologist or the morphologist is likely to be interested in. Manuals should supply the needs of either class.

The genetic relationship of parasites, F. D. KERN (*Amer. Jour. Bot.*, 2 (1915), No. 3, pp. 116-131).—This discussion lays emphasis on parasites as an aid in determining specific and generic relationships in their hosts. This is illustrated with examples drawn from the author's previous study (*E. S. R.*, 27, p. 424) on hosts as paralleling parasitic species of the genus *Gymnosporangium*.

Systematic relationships among the nodule bacteria of some legumes, R. KRÜGER (*Beiträge zur Artenfrage der Knöllchenbakterien einiger Leguminosen. Inaug. Diss., Univ. Leipzig, 1913, pp. 56; abs. in Ztschr. Bot.*, 6 (1914), No. 9, pp. 782, 783).—The author has been able by cultivation, it is claimed, to separate *Bacillus radicolica* into four groups according to the legumes with which they are associated, namely, *Lupinus perennis*, *L. angustifolius*, *L. luteus*, and *Ornithopus sativus*; *Vicia sativa* and *Pisum arvense*; *Medicago lupulina*, *M. sativa*, *Melilotus albus*, and *Trigonella fœnumgræcum*; and *Lotus uliginosus*, *Anthyllis vulneraria*, and *Tetragonolobus purpurea*.

No relationship was noted between *V. sativa* and *V. faba* in this regard, and *Phaseolus vulgaris*, *Trifolium pratense*, *Onobrychis sativa*, and *Soja hispida* showed no relationship among themselves or with the others studied in this respect.

Problems in soil bacteriology, J. G. LIPMAN (*Abs. in Science, n. ser.*, 42 (1915), No. 1079, p. 316).—Attention is called to the desirability of a further study of a number of problems in relation to soil bacteria, among them the location of species, their associative and antagonistic relations, their rôle in the formation of humus, and the effect of temperature, moisture, aeration, and other factors influencing their activity in the soil.

The effect of certain organic soil constituents on the fixation of nitrogen by *Azotobacter*, B. WILLIAMS (*Abs. in Science, n. ser.*, 42 (1915), No. 1079, pp. 320, 321).—This paper gives the results of a study of the effect of various organic compounds, such as are likely to be found in soils, on the growth of *Azotobacter*.

The results indicate that the fixation of nitrogen by *Azotobacter* is only slightly influenced by the compounds investigated. Hydroquinon and salicylic aldehyde were the most toxic of any compounds studied, while esculin, quinic acid, and borneol gave marked stimulation to the growth of the organism. As a rule, the effects of the compounds on the micro-organism were not in accord with what has been reported of their action on higher plants. Concentrations which are fatal to certain higher plants only slightly depressed fixation. Such compounds as nicotin, picolin, guanidin, and skatol exhibited toxic properties similar to those usually ascribed to these substances, though caffein stimulated the growth of the organism. Many of the nitrogenous compounds used, which have been reported as beneficial to higher plants, had a markedly depressive

effect on nitrogen fixation. In this respect the simpler compounds were more pronounced than were the more complex, and it is suggested that this condition is not one of toxicity, but that the nitrogen of the compounds was used in preference to that of the atmosphere. Urea, glycol, formamid, and allantoin were especially active in depressing fixation.

Selection of nitrogen compounds by *Aspergillus*, W. ZALESKI and D. PUKOW (*Ber. Deut. Bot. Gesell.*, 32 (1914), No. 7, pp. 479-483).—As a preliminary to a more general investigation regarding the selective power of mold fungi from among nitrogen compounds, the authors have studied the relative utilization by *Aspergillus* of nitrogenous material in case of ammonium and salts amino acids supplied in a nutritive solution containing also glucose and mineral salts.

It appears that in the presence of a good carbon source ammonia is a better nitrogen source for mold fungi than are amino acids individually, but it is thought that a suitable admixture of the latter may prove to be still better for this purpose.

Formation of albumin in yeast, W. ZALESKI and W. ISRAILSKY (*Ber. Deut. Bot. Gesell.*, 32 (1914), No. 7, pp. 472-479).—The results of a preliminary study of yeast supplied with nitrogen sources in different combinations are claimed to support the view that yeast forms its nitrogenous material not from ammonia or from amino acids separately but from a certain admixture thereof.

Theories of fermentation, C. L. ALSBERG (*Abs. in Science, n. ser.*, 42 (1915), No. 1080, p. 359).—According to the author, there are two types of theories of fermentation, one of which deals with the mechanism by which the substance fermented is converted into the end products of fermentation, while the other deals with the physiological rôle which fermentation plays in the life of the fermentation organism.

In the present paper it is suggested that fermentation is the expression of the metabolism of energy of a micro-organism. As an explanation of why a small mass of organisms converts a relatively large mass of material, the author calls attention to the energy requirements of the organisms, which possess a large surface area in comparison with their mass, and to the fact that there are excessive losses of heat due to radiation from the liquid medium in which the organisms live.

Albuminous crystalloids in potato leaves, HELENA HUBERT (*Österr. Bot. Ztschr.*, 64 (1914), No. 7, pp. 273-277).—The author reports that the formation of albuminous crystalloids is plentiful in young leaves of potato plants grown from tubers in darkness and moisture, but much less so in plants grown in light and that the crystalloids diminish rapidly in etiolated plants after these are exposed to light. The crystalloids, which appear only in the leaves, are abundant in the intumescences on the leaf surfaces, also in the interior portions of the leaf, when grown under glass, but they disappear with the shrinking of the intumescences.

Anthocyanin in plants, V. GRAFE (*Umschau*, 18 (1914), No. 32, pp. 643-646).—This is a discussion of contributions by several authors mentioned regarding the presence, composition, and significance of anthocyanins in plant cells.

A study of chloroplasts, A. P. PONOMAREW (*Ber. Deut. Bot. Gesell.*, 32 (1914), No. 7, pp. 483-488).—The author gives some details of a preliminary study of living chloroplasts as regards their structure, varying consistency, coagulation, vacuolation, chemical behavior, and evidences noted of colloidal characters.

A contribution to the physiological theory regarding chlorophyll, D. IWANOWSKI (*Ber. Deut. Bot. Gesell.*, 32 (1914), No. 7, pp. 433-447, fig. 1).—Concluding a further study (*E. S. R.*, 31, pp. 127, 128) of the relation between

light absorption and the production of coloring materials in leaves, the author states that the absorption of blue light waves is related to the presence of the yellow pigment, which weakens greatly the violet rays which are energetically absorbed by the photosynthetic pigments. These facts explain the protective influence, previously noted, of the yellow pigments on the photosynthetically active coloring material.

The curve of absorption in clear sunlight shows a second maximum of assimilative energy in the violet region, but its height is lessened by the presence of the yellow pigment.

Green plants are thus fitted by the properties of their pigments to assimilate carbon in direct sunlight without suffering excessive injury to their chlorophyll. They employ a portion of the energy of the less effective red rays for this purpose, these being readily absorbed, while the violet rays are in part suppressed by the yellow pigment.

Substances separated by plants in arid regions of Argentina, C. SPEGAZZINI (*An. Soc. Cient. Argentina*, 77 (1914), No. 3-4, pp. 151-158).—This is a discussion of plant efflorescences, exudations, and incrustations under arid conditions, as regards their production, properties, and probable significance.

Changes due to climate and soil in cultivated crops, J. BUKOVANSKY (*Wiener Landw. Ztg.*, 64 (1914), No. 93, pp. 823, 824, figs. 2).—It was found that severe losses in spring, despite promising early growth in case of clover from southern Europe as compared with that from more northerly regions, were correlated with the mode of growth of the smaller roots, which in the former variety radiated from a region near the surface, but in the latter branched mainly from the deeper portions of a strong tap root.

Phenological dates and meteorological data recorded by Thomas Mikesell between 1873 and 1912 at Wauseon, Ohio, J. W. SMITH (*Mo. Weather Rev.*, Sup. 2 (1915), pp. 23-93, pl. 1, fig. 1).—Phenological data are given of 16 different kinds of fruits, 20 varieties of field and garden crops, 48 species of forest trees, shrubs, and vines, and dates of blossoming of 114 different species of plants, for the period 1883-1912. In addition, tables are given showing the principal meteorological data and certain crop and fruit yields in the county where the observations were made. No attempt has been made to correlate the data regarding the weather conditions and the advance of vegetation, the object of the paper being to record this new series of observations for the use of students of the subject.

Studies in the physiology of germination, E. HEILPERN (*Österr. Bot. Ztschr.*, 64 (1914), No. 7, pp. 286-293, figs. 2).—In experiments with seeds of *Aethusa cynapium*, *Acer platanoides*, *Geranium pyrenaicum*, *Ranunculus acer*, *Oenothera biennis*, and *Silene acaulis*, all showing a rest period, it was found that no considerable influence was exerted on germination by exposure to snow, ice, water, or air at 0° C. regardless of the existence of a rest period.

As to duration, the rest period differed in different plants, appearing to be in some degree an individual property, but not to depend upon locality and date of harvesting in a given species.

Dimorphism as to fruit forms was shown by *Tragopogon dubius*, *T. orientalis*, and *T. porrifolius*, those of the first named showing also physiological dimorphism as regards germination.

The action of plant metabolism products on plants, I, II, W. STEGEMUND (*Biochem. Ztschr.*, 62 (1914), No. 5-6, pp. 299-386; *abs. in Jour. Chem. Soc. [London]*, 106 (1914), No. 620, I, pp. 787-789).—These two articles deal with the action of about 70 nitrogenous products on the germination of various seeds, the first part dealing with alkaloids and the second including glucosids, tannins,

and their cleavage products. The percentage germinating after treatment and the rate of growth of roots and stems were investigated in each case as affected by the different substances and the results given in connection with each.

Light intensity and substratum as related to germination, A. OTTENWÄLDER (*Ztschr. Bot.*, 6 (1914), No. 10, pp. 785-848, figs. 8).—Experimentation similar to that of Lehmann (E. S. R., 2S, p. 327) is said to have shown that germination of seeds depends largely upon temperature, but both this requirement and that of light are found to differ, not only in general with species, but individually with age and parentage. The light requirement as regards intensity is closely related to temperature, the former increasing as the latter is lowered. The illumination period is related also to temperature, but more closely to light intensity. Seeds which are sensitive to light are also strongly influenced by weak acids.

The hypothesis of a catalytic influence of light is said to have received support from these observations.

A bibliography is appended.

The influence of light from the mercury vapor lamp on the germination and early growth of plants, W. CARL (*Beitr. Biol. Pflanz.*, 12 (1914), No. 3, pp. 435-437, pl. 1).—The author states that ultraviolet rays were found to exercise an injurious influence on sprouting plants as regards both germination and subsequent development in the early stages. This is claimed not to be due to warmth or to ozone but to the chemical influence of the ultraviolet rays.

The influence of light on etiolated leaves, E. SCHÖNFELD (*Beitr. Biol. Pflanz.*, 12 (1914), No. 3, pp. 351-412, figs. 55).—Reporting experiments with light influence on numerous plants, mostly of familiar species, the author states that individuals whose leaves had remained small in darkness usually renewed growth measurably with access of light, this response, however, being weaker in older leaves and in general stronger in the younger parts. Beyond a certain point no response was obtainable.

On account of the fact that recovery may be limited to certain portions, abnormal leaf forms may result, some of which are described. Recovery of color and renewal of growth are held to be separate phenomena, the former always preceding. The longitudinal growth of parallel veined etiolated leaves when brought into the light is checked, but these show a tendency toward attainment of normal breadth.

A bibliography is appended.

The influence of humidity and illumination on growth in length of seedlings, HELENE JACOBI (*Österr. Bot. Ztschr.*, 64 (1914), No. 3-4, pp. 94-101; *abs. in Bot. Centbl.*, 126 (1914), No. 9, p. 212).—Continuing previous work (E. S. R., 2S, p. 227), the author has investigated the joint effects of moisture and light on plants.

It was found that in experiments carried out with bean seedlings in moist air where the product of light intensity by exposure period was a constant a larger value of the time factor was needed than heretofore to produce retardation of growth; that is, the presence of moisture decreased the effect of the intensity factor on the growth of the plant.

The influence of air movements on illumination of foliage, J. VON WIESNER (*Ber. Deut. Bot. Gesell.*, 32 (1914), No. 8, pp. 559-565).—This is a discussion of the tendencies noted of leaves on certain plants to assume positions habitual or advantageous in direct or in diffused light or to return to such positions after being disturbed by wind of longer or shorter duration and of the loss of this tendency in aging leaves.

Effect of high frequency currents on plants, E. HOMBERGER (*Umschau*, 18 (1914), No. 36, pp. 733-735, figs. 2; abs. in *Internat. Inst. Agr. [Rome], Mo. Bul. Agr. Intel. and Plant Diseases*, 5 (1914), No. 11, pp. 1430, 1431).—The author carried out experiments with several common vegetables along the same general lines as those followed by Lemström, Lodge, and others (E. S. R., 20, p. 930; 21, p. 317), by employing alternating electrical currents of very high potential and rapidity of oscillation. It is claimed that the large increase in growth and in chlorophyll formation was due to the oscillating field and not to heat generated by the current.

The influence of chloroform on assimilation by chlorophyll, K. VON KÖRÖSY (*Hoppe-Seyler's Ztschr. Physiol. Chem.*, 93 (1914), No. 1-2, pp. 145-153, fig. 1).—The author found in experiments with *Elodea canadensis* that a 0.074 per cent solution of chloroform lowered chlorophyll assimilation by this plant.

Internal factors regulating plant growth, R. DOSTÁL (*Biol. Listy*, 1914, p. 205; abs. in *Bot. Centbl.*, 125 (1914), No. 23, p. 585).—This is a study of the developmental correlations observable within the plant itself.

The author found that parts of a stem of *Scrophularia nodosa*, bearing a few leaves, when cultivated separately developed from the basal portions root-like structures, from the middle portions leaves, and from the terminal portions flower buds. It is held that under normal conditions the leaves regulate development in their axillary buds and affect likewise that of neighboring portions of the stem. The leaves exert an influence upon floral development. The activity of the cotyledons also shows a correlation with the development of their axillary and higher buds. This is probably to be ascribed to the organic material given up by the cotyledon, as on its exhaustion (especially in carbohydrates) the correlation decreases or disappears.

Green leaves do not appear to regulate stem development, but they do appear to influence root development, as do also other organs as a rule.

Cell adjustment following decapitation and inversion of shoot, F. NEEFF (*Ztschr. Bot.*, 6 (1914), No. 6, pp. 465-547, pl. 1, figs. 32).—This is a contribution to experimental anatomy of plants, being an account of studies, with bibliography, regarding the effect of decapitating or inverting a growing shoot on the laterals, as shown by the resulting position and arrangement of the cells, fibers, and tissues and the relations of the cambium thereto.

The rise of sap in trees, FARENHOLTZ (*Naturwissenschaften*, 2 (1914), No. 24, pp. 594, 595; abs. in *Bot. Centbl.*, 126 (1914), No. 21, p. 549).—This is a discussion of the more important views offered up to this time regarding the causes of sap ascent in trees.

Inventory of seeds and plants imported by the Office of Foreign Seed and Plant Introduction during the period from January 1 to March 31, 1913 (*U. S. Dept. Agr., Bur. Plant Indus. Inventory No. 34* (1915), pp. 51, pls. 6).—This inventory gives economic notes regarding about 400 plant introductions, the material being largely contributed by correspondents in various foreign countries who have sent the material either in response to requests or on their own initiative.

FIELD CROPS.

Management of irrigated land, F. KNORR (*Nebraska Sta. Bul.* 152 (1915), pp. 5-24).—This bulletin briefly discusses various phases of irrigation and gives results of the effect of fall irrigation on potatoes, corn, beets, barley, wheat, and oats for 1911, 1912, and 1913 at the Scottsbluff substation, in cooperation with the Bureau of Plant Industry of the U. S. Department of Agriculture.

The average gain in yield for each crop was, respectively, 2, 22, 15, 23, 19, and 15 per cent for the three years.

In a study to determine the best method of irrigating potatoes the following yields were obtained as averages for 1912, 1913, and 1914: Two hundred and ninety-six bu. per acre by irrigating every row and keeping the soil moist and the plants in a growing condition; 270 bu. per acre by beginning irrigation after the plants required water, then irrigating every row according to common farm practice; 239 bu. per acre by irrigating alternate rows at such times as the crop required water (at the first irrigation every other row was skipped, at the second irrigation the skipped rows were irrigated and the previously irrigated rows omitted, and so on throughout the season); 234 bu. per acre by irrigating every row but permitting the plants to suffer between irrigations; and 215 bu. per acre by irrigating every other row throughout the season. The rank in marketable tubers was 1, 2, 4, 3, and 5.

Data here presented that were collected by the U. S. Reclamation Service show that with barley, corn, oats, potatoes, rye, stock beets, sugar beets, and wheat, larger yields were obtained when the crops were grown on alfalfa stubble than when grown on land that had not been in alfalfa. In some cases the increase was over 100 per cent.

Sowing alfalfa in the spring with and without a nurse crop and in the grain stubble are noted as three successful methods that were tried. With the exception of the first crop it was found best to irrigate alfalfa after the hay was cut. The time of cutting alfalfa made no material difference as to the total yield obtained during the year, provided the irrigation was normal. Tests showed that three cuttings produced as much hay as four cuttings, provided the last cutting was made at the same time in both cases.

It was more profitable to plow under second or third alfalfa stubble than to plow under the whole crop in the production of sugar beets. In all instances of either spring or fall plowing of alfalfa stubble in various ways for sugar beets, the yield was not affected as long as the work was done well and the alfalfa crowns destroyed so as to prevent volunteer growth. Sugar beets planted in rows 18 and 20 in. apart were more successfully irrigated and in general produced more than rows spaced 24 and 28 in. apart.

County experiment farms in Ohio.—Annual reports for 1914, C. E. THORNE (*Ohio Sta. Bul.* 286 (1915), pp. 225-244, 246-291, figs. 8).—This bulletin comprises reports for 1914 of the work of the experiment farms located in Miami, Paulding, Hamilton, Clermont, and Washington counties in continuation of that previously noted (*E. S. R.*, 31, pp. 226, 430), with the exception of the Washington County experiment farm, the work of which is here reported for the first time. A brief outline of the work of these farms by C. W. Montgomery is included. The reports for the several farms give results of fertilizer and barnyard manure experiments with rotation crops including corn, oats, wheat, soy beans, clover, tobacco, and sugar beets, and of variety tests with corn, oats, wheat, and soy beans.

A general summary of the fertilizer work states that in every case, excepting at Paulding, acid phosphate has produced a marked increase of crop. "When the acid phosphate has been reinforced with muriate of potash there has been a further increase of crop in all the tests, excepting again that at Paulding, but the additional increase has not always been sufficient to cover the added cost of the fertilizer. At Wooster the increase in corn has abundantly justified the use of the potassium, while that of wheat has not. The residual increase in the clover and timothy, however, has been sufficient to justify the adding of the potassium salt, with a margin to spare, even when the cost of the potassium

has been more than twice as great as that of the phosphorus. At Strongsville the increase due to the potassium salt has not in any case been sufficient to cover the additional cost of the fertilizer, the average total gain for the addition of 260 lbs. of muriate of potash in each rotation being but \$1.39 over that produced by acid phosphate alone.

"Where the potassium salt has been added in the smaller quantities used in the other tests, the cost being 50 cts. per acre for each crop at Germantown, Carpenter, and Findlay, and \$1.25 per acre for each crop at the county experiment farms, this additional cost has been returned in the increase with a liberal margin in every crop, but the wheat crops have not always been sufficiently increased to pay for the potassium without the help of the residual effect on the clover following the wheat. Taking the entire rotation, however, the present indications are that on all these county experiment farms the use of such a combination of phosphorus and potassium as has been employed in these tests will produce a greater net gain per acre than will the phosphorus alone.

"The addition of nitrogen in nitrate of soda has been justified at Wooster in the total results of the rotation, although the increase of corn has not recovered the additional cost of the fertilizer. The smaller quantity of the nitrate used at the district and county experiment farms has been paid for in the increase at Carpenter only, the apparent increase of wheat in rotation 2 at the Miami county farm being offset by the low yield of corn, indicating that soil variation has as yet had more to do with the effect than nitrogen in the fertilizer. The average results of the two years' work on the Clermont county farm justify the addition of nitrogen to the fertilizer, and it is highly probable that these results will be confirmed by longer tests, as the soil of that farm had been depleted by a still longer period of exhaustive husbandry than that which had brought the Wooster farm to its present condition."

The addition of acid phosphate to farmyard manure at the rate of 40 lbs. to the ton of manure has given increased yields.

[Field crops] work of the Belle Fourche reclamation project experiment farm in 1914, B. AUNE (*U. S. Dept. Agr., Bur. Plant Indus., Work Belle Fourche Expt. Farm, 1914, pp. 1-6, 8-14, 16, fig. 1*).—This reports the continuation of work previously noted (*E. S. R., 32, p. 430*), and gives data on climatic and crop conditions of the project in South Dakota, together with acreage, yields, and farm values of crops produced in 1914, an inventory of live stock, and notes on cooperative work. Yields of the rotation crops are given for 1914 and the average yields compared with those of 1912 and 1913. The average sugar content of beets for 1912, 1913, and 1914 was 14.8, 19.1, and 22.1 per cent, respectively.

Data show a decided increase in yields of all crops in 1914 over the preceding seasons, except with potatoes.

"Beets after oats (manured) have given a higher average yield for the three years than beets after oats without manure. The difference, though, in favor of manured oats was not large until 1914, when the average of the plats after the manured oats was 1.3 tons higher than the average of the plats after oats without manure. Corn after beets has shown a decided effect of the preceding crop. In the seasons of 1913 and 1914 corn after beets had an unhealthy appearance during the early part of the summer and the yields obtained were comparatively low. Potatoes after manured beets have shown an increase in yield over potatoes after beets without manure, while potatoes after manured oats have not yielded any higher than potatoes after oats without manure. Spring wheat after alfalfa has produced high yields all three years."

In testing 14 different rates varying from 2.5 to 25 lbs. of seed per acre, the best yields of alfalfa generally were obtained on the plats where a light rate of seeding was used. From 4.5 to 6 lbs. per acre seemed satisfactory.

Early spring seeding of alfalfa was more satisfactory than late spring seeding, and better results were obtained with a nurse crop than without one. A decided advantage is noted in seeding alfalfa in late summer in grain stubble.

The net return in 1914 from a 12-acre alfalfa field on gumbo soil, from which the second cutting was made a seed crop, was \$37.70 per acre. Experiments in fall irrigation of alfalfa showed a slight difference in favor of the plats not fall irrigated. "As long as the fall irrigation has no detrimental effect on the alfalfa, it appears desirable to irrigate in a dry fall, in order to start the alfalfa early in the spring."

Variety tests with corn gave yields ranging from 31.5 to 45.4 bu. per acre. Experiments in spacing corn in rows 42 in. apart show that 14 and 17 in. in the row gave more satisfactory results than 7, 10, or 21 in.

The work of the San Antonio experiment farm in 1914, S. H. HASTINGS (*U. S. Dept. Agr., Bur. Plant Indus., Work San Antonio Expt. Farm, 1914, pp. 16, figs. 6*).—This reports work in continuation of that previously noted (*E. S. R.*, 32, p. 332), and aside from giving data on the climatic conditions for the year at San Antonio, Tex., data are included on rotation experiments, experiments with cotton, milo maize, Canada field peas, Sudan grass, corn, and cowpeas, and experiments in pasturing oats, and brief notes on horticultural work.

The value of rotation is shown in the higher yields of crops in 2-year rotations rather than with the same crops grown continuously, except in instances where cotton followed sorghum.

"The effect of manure on crop yields at San Antonio under the conditions during the years 1910 to 1914 have not been consistently significant. The yields of cotton, corn, and milo maize have generally been slightly increased by manuring. The increases, however, have not been sufficient as yet to justify the expense of the treatment. Manure has caused a slight decrease in the yield of oats following manured cotton."

As a result of testing the single-stalk method of growing cotton (*E. S. R.*, 32, p. 434), it is stated that "in all cases the close-spaced rows gave higher yields than adjoining rows in which the plants were wide spaced, the range of increase being from 88 to 125 per cent in favor of the close-spaced rows. Results with cotton thinned 25, 41, and 51 days after planting were somewhat inconclusive. Planting cotton in rows 4 ft. apart resulted in larger yields than spacing rows 3, 5, or 6 ft. apart.

Results of experiments with Canada field peas, including a test of 70 varieties, have shown this crop to be valuable as a green-manure crop and for hay.

It is noted that "oats can be pastured up to January without seriously injuring the hay crop. It is advisable, therefore, to plant early in the fall, at least as early as the first of October. Pasturing the oats severely in the winter and early spring has a very marked effect in reducing the yields of hay or grain, but this in turn may be offset by returns from the pasture."

Division of field husbandry.—Summary of results, 1914, W. L. GRAHAM ET AL. (*Canada Expt. Farms Bul. 83 (1915), pp. 55*).—This bulletin is a general summary of continued work previously noted (*E. S. R.*, 32, p. 530), giving data as to yields, cost of production, rotation of crops, and the results of different cultural methods obtained on the various experiment farms of Canada. The crops used in these experiments were mangels, turnips, corn, hay, wheat, oats, barley, potatoes, buckwheat, timothy hay, peas, alfalfa, flax, and clover. The cost of production on the various farms is given as follows: Barley \$12.78

per acre, 23.7 cts. per bushel; potatoes \$49.25 per acre, 21 cts. per bushel; wheat \$13.78 per acre, 43.7 cts. per bushel; hay from \$11.90 to \$13.25 per acre and from \$5.70 to \$5.86 per ton; corn silage from \$21.97 to \$30.75 per acre and from \$1.91 to \$5.36 per ton; turnips from \$28.98 to \$45.56 per acre, from \$1.86 to \$2.50 per ton, from 5.4 to 8.73 cts. per bushel; oats from \$15.90 to \$18.30 per acre and from 24.7 to 33 cts. per bushel.

Fertilizer tests at the central farm in a rotation of mangels, oats, clover hay, and timothy have shown a distinct advantage of barnyard manure alone over commercial fertilizer on this soil, but point to the possibility of combining the two to good advantage if the manure is scarce or high in price. Fertilizer tests with oats, potatoes, and turnips, and variety tests with oats, turnips, sugar beets, and carrots, are also reported.

Report of the Bavarian Cereal Breeding Station in Weißenstephan, 1912-13, L. KIESSLING (*Landw. Jahrb. Bayern, 4 (1914), No. 6, pp. 576-633*).—This summarizes work in breeding and variety testing of cereals for 1912 and 1913.

Results of variety tests of wheat, oats, and rye, G. M. GARREN (*North Carolina Sta. Bul. 232 (1915), pp. 3-28*).—The results given in this bulletin include tests made at the Buncombe, Iredell, Blantyre, and central station farms, covering periods ranging from 1 to 10 years and presented in tabular form. It is noted that with wheat practically all of the evidence of these experiments is in favor of the smooth varieties outyielding the bearded, and that home-grown seed also outyielded that imported from outside the immediate vicinity.

"Abruzzi rye has been found to far excel the common rye in yield of both grain and straw. It is also ten days to two weeks earlier. It is especially recommended for those who wish to sow rye for late fall or early spring pasture, or for winter cover crop.

"There has been found, upon the whole, about 50 per cent difference between October sown and December sown wheat on the Iredell test farm. In every instance there is a progressive decrease in yield from the sowing on October 10 to that on December 21. This is based on two years' tests and the results will doubtless not be changed by future experiments. Wheat in the vicinity of the Iredell test farm should be sown as early in October as danger from the Hessian fly will permit."

Storing the grain crop, J. F. HOFFMANN (*Landw. Hefte, No. 28 (1915), pp. 40, figs. 10*).—A treatise on methods for the artificial drying of grains, with illustrations of various types of dryers.

Zellers' hay and coal table (*Hooper, Nebr.: The Zellers Publishing Co., 1915, pp. 51*).—This is a table giving the values of pounds and tons up to two tons with prices ranging from \$2 to \$14.25 per ton.

Stacks, E. RABATÉ (*Vie Agr. et Ruralc, 5 (1915), No. 13, pp. 229-234, figs. 6*).—This article gives the results of a study of the site, form, dimensions, construction, cover, and cubature of stacks. Mathematical formulas and diagrams are used to calculate scientifically the true proportions and cubature of different forms of stacks of hay and cereals.

Selection of yellow alfalfa at the Krasnokutsk Experimental Station, P. N. KONSTANTINOV (*Selsk. Khoz. i L'isov., 246 (1914), Oct., pp. 173-191*).—This gives the results of selection and hybridization work with *Medicago falcata* in an effort to secure a plant sufficiently hardy to withstand the soil and climatic conditions of southeastern European Russia and sufficiently prolific to become a valuable forage crop.

The composition of yellow alfalfa at various stages of development was found to be as follows:

Composition of yellow alfalfa at various stages of growth.

Stage of growth.	Protein.	Fat.	Nitrogen-free extract.	Crude fiber.	Ash.
	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>
Beginning of bloom.....	16.42	5.19	36.00	34.62	7.77
Blooming.....	14.70	3.97	36.89	37.64	6.80
Ripening of seeds.....	13.03	3.11	37.11	39.97	6.78
Dying.....	7.65	2.42	35.76	49.52	4.65

Consideration of the parents and the hybrids showed that an upright growth was made by *M. sativa* and a rather trailing growth by the yellow alfalfa, while the hybrids were intermediate in this character; the hybrids were also intermediate between the parents in thickness of growth and height. The yellow alfalfa bloomed most uniformly. In the coloring and the width of the leaves and the drooping attitude of the leaves, the hybrid plants ranged between the parents. In abundance of foliage the hybrids approached the yellow alfalfa, while in shape and coloring of the seed the hybrid ranged between the parents.

A special type of cage for the isolation of the flower stalk of mother beets, O. MUNERATI (*Atti R. Accad. Lincei, Rend. Cl. Sci. Fis., Mat. e Nat.* 5, ser., 23 (1914), II, No. 12, pp. 616-620, figs. 3).—This describes a cage consisting of a square-framed top covered with wire netting to which is attached a muslin curtain that surrounds the stalk and is secured around it at its base. The whole is supported by two sticks driven into the ground on opposite sides of the plant. It is noted that this type of cage effectively prevents cross-pollination, yet admits air and light and allows of easy access to the flower stalk for hand-pollination or examination.

Red clover seed production: Pollination studies, J. M. WESTGATE and H. S. COE (*U. S. Dept. Agr. Bul.* 289 (1915), pp. 31, figs. 7).—This bulletin briefly reviews the work of previous investigators and describes the structure, development, and fertilization of red clover flowers as well as the experimental methods employed by the authors in securing cross-pollination and self-pollination at Ames, Iowa (in collaboration with H. D. Hughes, L. H. Pammell, and J. N. Martin), Lafayette, Ind. (in collaboration with A. T. Wiancko and F. E. Robbins), and Arlington, Va.

In regard to potency of pollen in self-pollination it is noted that "an examination of 30 flowers which had been self-pollinated for 55 hours showed good germination on the stigmas, but no fertilization. The number of pollen grains germinating on the stigmas ranged from 3 to 25 in each of the 30 flowers. The tubes had made a slow growth and none exceeded 4 mm. in length. An examination of 20 flowers which had been self-pollinated for 90 hours showed that one pollen tube had attained a length of 7.5 mm., while the others were 5 mm. or less in length. At this rate of growth the longest tube would have required about 48 hours more to reach the ovules, or about six days to traverse the entire distance from stigma to ovule. Flowers examined four days after springing the carinas showed the eggs in a disintegrated condition. It is therefore probable that in case of self-pollination the pollen tubes do not reach the ovules in time to effect fertilization. An examination of the 30 flowers which

had been cross-pollinated for 55 hours showed that fertilization had taken place in all of them."

The use of the thumb and finger or of a toothpick or toothbrush in artificial manipulation of the flower resulted in practically no seed in covered heads and in a reduced number in exposed heads as compared with those not covered and not manipulated.

As results of covering untreated heads of clover with tarlatan it is noted that "since no more seed was produced by these heads than may be accounted for by insects working on the flowers when they were occasionally exposed for a short time on account of rains or grasshoppers, we may say that clover flowers must be pollinated by some agency before any seed is produced."

Clover heads covered before any flowers opened and kept covered, except while being artificially self-pollinated, until mature produced an average of 0.16 seed per head in 1911 and 0.09 in 1912. One hundred and twenty-five heads were worked in the first instance and 170 in the second. Not a single seed was produced in flowers pollinated with pollen from another head on the same primary branch, and only one seed was produced in using pollen from a head on a different primary branch of the same plant when 200 flowers were used on 10 heads. Fourteen and three-tenths seeds per head were produced in 13 heads, in which 20 flowers each were pollinated from a separate plant. "The results obtained in the last three experiments, as well as with all preceding ones, show that clover is practically self-sterile and that pollen must come from a separate plant in order to effect fertilization."

"The bumblebee is an efficient cross-pollinator of red clover. Bumblebees are able to pollinate from 30 to 35 flowers a minute. The honeybee proved to be as efficient a cross-pollinator of red clover as the bumblebee in 1911. When the precipitation was considerably below normal in June, July, and August, 1911, and but few nectar-producing plants were to be found, honeybees collected large quantities of pollen from red clover. In order to collect pollen they must spring the keels of the flowers. In doing this they cross-pollinate the flowers.

"A clover cross-pollinating machine which was offered for sale on the market did not prove to be an efficient cross-pollinator of red clover. The various types of hand-operated brushes which were used did not prove efficient as cross-pollinators of red clover. In nearly all cases where these brushes were used the seed yield was decreased instead of increased. This was undoubtedly due to the bristles of the brushes injuring the flowers, since the average seed yield of the plats which received these treatments with the brushes was lower than that of the plats which received but one treatment."

A bibliography of nearly 50 titles is appended.

Custom ginning as a factor in cotton-seed deterioration, D. A. SAUNDERS and P. V. CARDON (*U. S. Dept. Agr. Bul. 288 (1915), pp. 8, figs. 5*).—This bulletin gives the results of a test at Greenville, Tex., to determine the amount of mixing of cotton seed that may occur at the gin. The amounts of red seeds that appeared in samples of seeds taken at 5, 10, 15, 20, 25, and 30 minutes after the starting of the gin, in which the seed roll in the roll box had been stained red, were 52 per cent, 17.1, 7.4, 2.8, 0.5, and 0.1, respectively.

"It has been shown that no less than 14 to 16 per cent, and probably much more, of the seed delivered to a patron at custom gins as ordinarily operated is seed of the variety ginned just previous to the arrival of his cotton. The results indicate also that some seeds from the second bale preceding are likely to appear in the seed delivered to the patron. This means that if different varieties are being ginned consecutively a patron will receive in the seed delivered to him at the gin an admixture of at least three varieties. It is apparent that if

such seed is planted opportunity is afforded for a vast amount of cross-fertilization in the field, and deterioration begins."

It is noted that mixing may also occur to a small extent in the flues and in the distributing, cleaning, and feeding devices.

As ways of minimizing the amount of mixing it is suggested that the patron cooperate with the ginner. The flues, feeders, and cleaners should be made as clean as possible and the roll in the roll box should be dropped before ginning to secure seed for seeding purposes.

A study of inheritance in the cotton hybrid, Sea Island and native St. Croix, S. C. HARLAND (*Rpt. Agr. Expt. Sta. St. Croix, 1913-14, pp. 50-60, pl. 1*).—This article gives detailed descriptions of a native St. Croix and a Sea Island "chance" variety of cotton and the F_1 and F_2 generation hybrids resulting from a cross between these two varieties. The characters described include bracts, boll characters, calyx, and lint characters.

Experiments with cotton in Sicily in 1914, A. BORZÌ (*Bol. R. Giard. Colon. Palermo, 2 (1915), No. 2, pp. 67-84*).—Tests of 11 varieties showed a range of from 32 to 35 per cent in yield of lint. In fertilizer tests with 600 kg. of superphosphate per hectare there was produced 1,417 kg. of seed cotton, which was a larger yield than with other fertilizers, including sulphate of potash, cyanamid, and barnyard manure. Descriptions of the most promising varieties are given.

Variation in the male hop, Humulus lupulus, H. WORMALD (*Jour. Agr. Sci. [England], 7 (1915), No. 2, pp. 175-196, pl. 1*).—This gives results of examinations of male hop plants of both English and Oregon origin.

The hops were found to vary in time of flowering and in characteristics of the bine, leaves, laterals (inflorescences), stipules, and flowers. The following type characters were discovered: (1) Time of flowering—early, medium, and late; (2) color of bine—green and red; (3) length of laterals—long and lax, short and dense; and (4) glands on the leaves—numerous and few.

Classification of broom millets, M. G. SIRÛSOV (*Selsk. Khoz. i Lîsov., 246 (1914), Dec., pp. 556-573, figs. 4*).—The author arranges about 40 varieties of broom millet into three groups, viz. *Miliaceum effusum*, *M. contractum* or *M. nutans*, and *M. compactum*, based upon the color of the grain. It is noted that a flower required about 27 minutes to open, the greatest activity taking place between 11 a. m. and noon.

Observations on potato culture, V. G. KOTELNIKOV (*Selsk. Khoz. i Lîsov., 246 (1914), Oct., pp. 221-232*).—It is noted that large tubers used as seed produced larger yields, but that the net profit was not so great as when smaller tubers, averaging about 2 oz. each, were planted. Experiments showed that the vegetative energy of smaller tubers was greater by 7 to 11 per cent and that a thicker planting of two small tubers in the same hill gave 30 per cent more yield than larger ones planted more thinly.

Prairie grass, W. S. HILL (*Jour. Agr. [New Zeal.], 10 (1915), No. 4, pp. 313-318, figs. 4*).—This notes the improvement by selection of *Bromus unioloides* at the Moumahaki Experimental Farm. The yield has been increased from 100 to 183, or nearly doubled.

The culture of rice in California, C. E. CHAMBLISS and E. L. ADAMS (*U. S. Dept. Agr., Farmers' Bul. 688 (1915), pp. 20, figs. 7*).—This contains recommendations based upon the results obtained at the Biggs Rice Field Station and a study of the conditions under which rice has been grown in California. It covers preparation of the seed bed and of the seed, manner of seeding, irrigation and drainage, methods of harvesting and thrashing, cost of production, varieties (including variety tests), methods of improvement of the crop, notes on rice products, and eradication of weeds.

Rye grass culture, H. MAYER GMELIN (*Medcd. Rijks Hoogere Land, Tuin en Boschbouwsch.* [Wageningen], 8 (1915), No. 4, pp. 161-195).—Results are given of cooperative experiments with several farmers to demonstrate the relative values of ordinary English rye grass, Improved English rye grass, and Italian rye grass. The average yields of hay for 1914 were, respectively, 295.25 kg. (3 cuttings), 318.25 kg. (3 cuttings), and 365.8 kg. (2 cuttings) per 100 square meters (119.6 sq. yds.).

Uses of sorghum grain, C. R. BALL and B. E. ROTHIGER (*U. S. Dept. Agr., Farmers' Bul.* 686 (1915), pp. 16, figs. 12).—This discusses the uses of sorghum grain as a feedstuff and as a food, with data as to the digestibility, preparation, and storage of the grain.

Statistical data also show the value and acreage of grain sorghums in parts of Kansas and Oklahoma in comparison with the corn crop.

Chemical analyses of air-dry samples of various grain-sorghum varieties grown at the Amarillo Cereal Field Station, Amarillo, Tex., from 1908 to 1912, inclusive, are reported and summarized below:

Composition of various grain sorghums.

Kind of sorghum.	Number of analyses.	Water.	Protein (N×6.25).	Fat.	Carbo- hy- drates.	Fiber.	Ash.	Weight.	
								1,000 kernels.	Bushel.
Milo maize.....	67	<i>Per ct.</i> 9.32	<i>Per ct.</i> 12.54	<i>Per ct.</i> 3.15	<i>Per ct.</i> 71.89	<i>Per ct.</i> 1.48	<i>Per ct.</i> 1.62	<i>Grams.</i> 36.1	<i>Lbs.</i> 58.1
Dwarf milo maize.....	55	9.38	12.16	3.27	72.09	1.47	1.63	31.4	58.2
Average of milo maize...	122	9.35	12.37	3.21	71.97	1.48	1.62	34.0	58.1
Feterita.....	8	9.58	14.00	2.90	70.32	1.48	1.72	32.2	55.9

Dwarf blackhull kafir corn.....	13	9.95	13.09	3.25	70.49	1.52	1.70	16.6	58.7
Red kafir.....	37	9.56	12.01	3.16	72.03	1.51	1.73	18.5	58.3
Average of kafir corn....	128	9.61	13.39	3.35	70.33	1.55	1.76	20.1	58.2
Shallu.....	10	10.38	15.17	3.69	66.86	1.92	1.98	15.1	57.9
Grand average of all va- rieties.....	268	9.52	13.01	3.29	70.95	1.53	1.70	26.6	58.1

Studies in Indian sugar canes.—I, Punjab canes, C. A. BARBER (*Mem. Dept. Agr. India, Bot. Ser.*, 7 (1915), No. 1, pp. 112, pls. 19, fig. 1).—The classes of cane found in the Punjab are given. The morphological characters used in the description of the classes of cane are cane measurements, color of cane, and characters of the joint, bud, leafy shoot, leaf sheath, and lamina.

Morphological study of variation in wheats with special reference to spike form, L. DETZEL (*Landw. Jahrb. Bayern*, 4 (1914), No. 10, pp. 839-902, pls. 27, figs. 5).—This gives data secured by measurements of the length, thickness, and weight of internodes of stems of wheat plants, and discusses the tillering and the relation of parts of the plants to the structure of the spike. An apparatus for measuring the internodes of the spike is described, also ten types of spikes on the basis of the structure and form of the spike. "A close relationship exists between the general morphological structure of the plant and the minor forms of the plant parts, which relationship can be slightly modified by certain influences."

Inheritance of awn color in wheats, L. KIESSLING ET AL. (*Landw. Jahrb. Bayern*, 4 (1914), No. 2, pp. 102-170).—This work reviews previous investigations along this line and gives the results of studying the inheritance of the white, yellow, light brown, and brown colors in the awns of wheats hybridized primarily for other purposes, since 1908. These colors or the factors producing them seem to have followed the theoretical ratios very closely, i. e., 1:3, 1:3:3:9 and 1:3(×3):9(×3):27.

Report of the division of agronomy and botany for 1915, J. L. BURGESS (*Bul. N. C. Dept. Agr.*, 36 (1915), No. 9, pp. 4-82).—Results are given of the examination and testing of 1,011 samples of farm seeds and 445 samples of vegetable seeds during 1915 according to the North Carolina Pure Seed Act.

A device for sampling grain, seeds, and other material, E. G. BOERNER (*U. S. Dept. Agr. Bul.* 287 (1915), pp. 4, figs. 6).—This bulletin gives a description of the mechanical structure and method of operation of a device "developed primarily to meet the demands of grain and seed dealers and laboratory workers for securing a reliable sample of grain or seed from a larger portion of the material to be examined, graded, or analyzed. It can also be used for sampling flour, meal, feeds, coal, ore, or any other material of like kind for examination or analysis and to mix or blend and divide two or more streams of unlike material of the kind specified, so that the two resulting streams will be a thorough mixture of the original two or more kinds of material. Another application of the device which should be of special interest to the grain trade is that a sample can be divided so that one-half can be used for testing and grading and the duplicate half either turned over to the seller or to the buyer of the grain or retained for future reference."

The operation of the device does not require power of any kind, gravity being all that is necessary to make the material pass through it.

Eradication of ferns from pasture lands in the eastern United States, H. R. Cox (*U. S. Dept. Agr., Farmers' Bul.* 687 (1915), pp. 12, figs. 8).—This gives results of experiments conducted in southern New York to eradicate the hay-scented fern (*Dennstaedtia punctilobula*). It was found that cutting off the tops close to the surface of the ground twice a year for two years would kill out nearly all of the ferns.

Experiments were made in 1912 and 1913 to test the efficacy of spraying as compared with cutting and to learn the best method of obtaining a stand of grass and clover on the fern-infested areas. The spray materials used were solutions of salt, arsenite of soda, and iron sulphate. These materials were used in quantities of equal value. The results of these tests showed the following facts:

"Salt is the best spray material of the three. With ferns at an average degree of thickness on the land, 150 lbs. of salt dissolved in 60 gal. or more of water to the acre for each application are sufficient. Two sprayings a year are about as effective as four, and are to be recommended. Cutting is somewhat cheaper than spraying. Furthermore, the cutting does not interfere with young clover and grass coming in on the infested patches after the first treatment. This method, therefore, is to be recommended in preference to spraying in most situations. In some places the land is so stony as to interfere with cutting, in which case spraying may be the best method. It was found that scattering seed on the patches where ferns had grown was the most important means of getting a stand of grass and clover, and that liming and fertilizing in addition to the seeding were of considerable benefit."

It is noted that similar methods would probably be equally effective in eradicating the brake (*Pteris aquilina*).

HORTICULTURE.

[Report on horticultural investigations], B. AUNE (*U. S. Dept. Agr., Bur. Plant Indus., Work Belle Fourche Expt. Farm, 1914, pp. 14, 15*).—A variety list is given of orchard and small fruits and ornamental trees and shrubs planted on the Belle Fourche Experiment Farm in 1914, together with a brief note on the condition of trees and shrubs previously planted.

Onions, R. W. JORDAN (*St. Paul, Minn.: Webb Publishing Co., 1915, pp. 95, figs. 41*).—A practical treatise on onion culture which discusses the onion with reference to its history, botany, importance, climatic and soil requirements, varieties, importance of good seed, fertilizers preparation of seed bed and seed planting, different types of onion growing, care and management of the crop, harvesting storing marketing yield and cost of growing and onion pests.

Onion cultivation, F. WATTS (*Imp. Dept. Agr. West Indies Pamphlet 78 (1915), pp. 30*).—A concise treatise on the growing, harvesting, and marketing of onions.

Some tests of tomatoes, L. B. UICHANCO (*Philippine Agr. and Forester, 4 (1915), No. 3, pp. 59-68, 70-80*).—An account is given of tomato growing in the Philippine Islands, including a discussion of insect pests and diseases, and data on variety, pruning, training, fertilizer, irrigation, and transplanting tests.

A bibliography on tomatoes and tomato culture is appended.

Rail shipments and distribution of fresh tomatoes, 1914, W. A. SHERMAN, P. FROELICH, and H. F. WALKER (*U. S. Dept. Agr. Bul. 290 (1915), pp. 12, pl. 1, fig. 1*).—In this bulletin an effort has been made to list largely by railroad stations the actual shipments of tomatoes for table use in 1914, the returns being incomplete in some cases owing to the failure to receive reports from certain shipping agents. In addition to tabular data for the various States, the data are also presented in the form of a map and charts, all of the areas shipping at a given period being grouped in a zone and thus showing the various competing areas as well as the dates of heaviest crop movement.

The total reported shipments of table stock for 1914 was 11,995 carloads, nearly one-half of the entire crop being shipped from the State of Florida. The States next in importance are Mississippi, New Jersey, and Texas, each shipping from 1,100 to 1,500 cars. It has been estimated that a somewhat greater number of tomatoes is grown for canneries, catsup factories, etc., than for table use.

Pruning (*Oregon Sta. Bul. 130 (1915), pp. 72, figs. 58*).—This bulletin is comprised of five separate articles, as follows: Plant Physiology as Related to Pruning, by W. M. Atwood (pp. 4-11), in which the author calls attention to the various conditions which surround the tree and which are often sufficiently effective to modify or do away entirely with the beneficial effects of thorough pruning practiced without regard to the other conditions; The Study of Fruit Buds, by E. J. Kraus (pp. 12-21), in which a discussion is given of the nature of fruit-bud development and location of buds on different classes of orchard trees, and a table is included showing the relation of position of bloom to bearing in the commoner varieties of Oregon apples and pears; Pruning Young Trees, by C. I. Lewis (pp. 22-47), in which consideration is given to the principles of pruning and their application to young nonbearing and bearing trees of various orchard fruits; and Pruning the Bearing Apple and Pear Tree (pp. 48-60) and Pruning the Bearing Prune Tree (pp. 61-72), both by V. R. Gardner.

A complete work on the pruning of fruit trees, J. F. MOODY (*Perth, Western Australia: Govt., 1912, pp. 135, figs. 175*).—A treatise on the pruning of all kinds of fruits and nuts grown in Western Australia.

New dosage tables, C. W. WOODWORTH (*California Sta. Bul. 257 (1915), pp. 3-16, figs. 3*).—A new principle applicable to the construction of dosage tables was discovered while making a careful comparison of the rate of charge in the dose necessary to compensate for the differences in leakage. The principle is that an arithmetical series of leakages is related to a geometrical series of dosages and both correspond to the same complex series of sizes of tents.

This bulletin discusses the application of the above principle to the construction of dosage tables and points out the errors in the tables commonly used. A set of tables based on the new principle is given and discussed.

The fruits of Germany (*Deutschland's Obstsorten, 7 (1911), I, Nos. 19, pls. 8, figs. 4; 20, pls. 8, figs. 5; 21, pls. 8, figs. 5; II, Nos. 22, pls. 4, figs. 3; 23, pls. 4, fig. 1; 24, pls. 8, figs. 4; 8 (1912), I, Nos. 25, pls. 8, figs. 4; 26, pls. 8, figs. 4; 27, pls. 8, figs. 3; II, Nos. 28, pls. 12, figs. 6; 29, pls. 12, figs. 4; 30, pls. 12, figs. 5; (1913), I, Nos. 31, pls. 8, figs. 5; 32, pls. 8, figs. 6; 33, pls. 8, figs. 6; 12 [1913], Nos. 34-36, pls. 36, figs. 14; with descriptive text*).—A continuation of serial accounts of German fruits started in 1905 and consisting of sets of three parts with descriptions of four varieties of fruit in each part (E. S. R., 24, p. 641). The annual sets of the years noted continue descriptions of pear and apple varieties and also describe a number of currants, gooseberries, and cherries. The descriptions and illustrations follow the arrangement in the sets previously noted.

Recent progress in fruit production in Hungary, D. ANGYAL and J. GYÖRY (*Internat. Inst. Agr. [Rome], Mo. Bul. Agr. Inocl. and Plant Diseases, 6 (1915), No. 5, pp. 652-657*).—A short account of the fruit industry in Hungary with reference to climatic conditions, distribution of the chief species of fruit trees, native and foreign varieties, area of orchard lands and estimated yields, research work and education, state encouragement of the fruit industry, and associations.

Fruit packing and the marketing and exporting of fruit, J. F. MOODY and J. RAMAGE (*West. Aust. Dept. Agr. Bul. 46 (1915), pp. 77, figs. 108*).—A treatise on the packing and marketing of citrus and deciduous fruits with special reference to the preparation of fruit for the export trade.

The pollination of the pomaceous fruits.—II, Fruit bud development of the apple, F. C. BRADFORD (*Oregon Sta. Bul. 129 (1915), pp. 10, pls. 6*).—This is the second of a series of studies of the pollination of pomaceous fruit (E. S. R., 29, p. 541).

In the present bulletin the author describes and illustrates with a series of plates the development of fruit buds of the Yellow Newtown apple. Buds were gathered throughout the work in six separate classes as follows: Axillary buds on the newest wood; terminal buds on the newest wood; buds from young spurs on second-year wood which had not borne fruit but seemed likely to bear in the following year; buds from spurs which were bearing in the current year; buds from spurs which had borne previously but had not blossomed in the current season, in other words, were "resting a year;" and buds from spurs which had blossomed but which had not set fruit, or having set fruit, had lost it early through dropping or thinning. Consideration is given to fruit bud differentiation in these various classes. A bibliography of literature cited is appended.

The earliest differentiation in fruit buds was visible during the first ten days of July, there being possibly a slight variation from year to year. Samples

from material gathered throughout a period of three years show very little, if any, difference between the stages reached at a given date in different years until well toward blossoming time, when the buds apparently become more responsive to external conditions. In the buds under observation the sepals, petals, and outermost cycle of stamens were easily recognizable by the fifth of August. By the middle of September the petals have become longer and wider, the stamens show frequently the bi-lobed appearance, the other two cycles of stamens have appeared and are well differentiated, and in many cases the carpels are already of fair size. Between this time and the last of November the most striking change is in the carpels, which by the latter date have enlarged considerably. Carpels are also beginning at this time in the side buds. Material gathered the middle of February showed little or no change in the terminal blossoms but pollen mother-cell formation in the side buds is evident. During February and March the pistils begin to push up rapidly and the ovules appear. The petals and stamens appear to have completed their development and to be awaiting the expanding of the blossoms.

A partial attempt was made to ascertain whether there is any difference among varieties in the time of fruit bud formation. The buds were examined from a number of different varieties on August 7, 1913. Although no conclusion can be drawn from this study the work as far as it went showed beyond probability that there is some little difference between varieties in their respective times of fruit bud formation, or at least as manifested in the development of the bud at the time when the samples were taken. In relation to the periods of ripening or to the times of blossoming the relative development in August has no exact correspondence. There is, however, more agreement with times of blossoming than with the period of ripening. A hasty examination of material gathered from the same trees in December, 1913, indicated an approach to a uniform winter stage for the different varieties.

An apple orchard survey of Berkeley County, E. C. AUCHTER (*West Virginia Sta. Bul. 151 (1915), pp. 3-75, pl. 1, figs. 25*).—This bulletin presents the results of a survey of the commercial apple orchards in Berkeley County, made during the summers of 1912 and 1913. Information is also given relative to the importance and distribution of the other fruit industries in Berkeley County, together with statistics on the fruit industries of West Virginia as a whole.

The survey included a total of 247 orchards of 5 acres or more and comprising 11,204.6 acres. Sixty per cent of these trees had not reached bearing age. Only 6 per cent of the total apple trees in the county were over 18 years of age. The largest yields and incomes were obtained from those orchards between 19 and 22 years of age. Only a limited amount of data was secured on orchards older than this. The commercial orchards varied in size from 1 to 487 acres. The typical orchard is about 15 acres in area, although the average-sized orchard due to so many large company orchards is 45 acres. Although sufficient data could not be obtained to warrant conclusions as to the relation of size of orchard to yield and income, the survey indicates that the largest orchards are not the most profitable.

The exposure or slope of the orchards is not an important factor in Berkeley County, since the sites are not steep or hilly. Eighty and five-tenths per cent of the orchards were planted by the square system, usually 30 by 30 ft. apart, although the tendency in later years was to plant 33 by 33 or 36 by 36 ft. apart. Generally only 3 or 4 varieties were found in a commercial orchard. Most of the bearing trees are Ben Davis, York Imperial, Grimes, and Arkansas (Mammoth Black Twig). In recent planting there is a tendency to eliminate Ben Davis and cut down the number of York Imperials, substituting such varieties as Stayman, Winesap, Jonathan, and Delicious.

Only a limited amount of data was obtained from company and rented orchards, but the survey indicates that those orchards managed by the owners themselves are giving the largest yields and incomes. The largest yields and incomes are being obtained on the average from soils of limestone origin. Clean cultivation with cover crops is the popular method of handling orchard soils. The 3-year-average income for orchards that have been cultivated 5 years or more since bearing is 108.3 per cent greater than for those orchards which have been in sod continually for the same length of time. The nonbearing orchards are generally intercropped with corn, although in many a 3-year rotation of corn, wheat, and hay is used. Stable manure on sod orchards gave the highest yield, while in cultivated orchards about the same yields were obtained from the use of either manure or commercial fertilizer. The greatest yields were obtained when both were used.

Although about 80 per cent of the orchards are pruned in the spring, pruning has not been practiced systematically and in most cases is poorly done. The most common insects found are San José scale, codling moth, green aphid, and woolly aphid, all being well controlled except the woolly aphid on the roots. The most troublesome diseases are collar blight, apple or cedar rust, and leaf spot. Black rot and twig blight are serious in some orchards. The collar blight is especially bad on the Grimes. Practically every orchardist in the country sprays. Lime-sulphur and arsenate of lead is the mixture generally used.

Data are given on the cost of labor and various orchard operations. The cost of producing a barrel of apples was \$1.25. The 3-year-average gross price per barrel was \$2.25, leaving a net profit of \$1 per barrel, and with a 3-year average yield of 40.2 bbls. per acre the net profit per acre was \$40.20. About 50 per cent of the orchards in the county are producing below the average in yield and income, others are yielding twice as much as the average.

The fertilization of peach orchards, W. H. ALDERMAN (*West Virginia Sta. Bul. 150 (1915), pp. 3-39, figs. 10*).—This bulletin describes three cooperative fertilizer experiments with peaches. The first was started by L. C. Corbett in 1899 in the Miller orchards at Paw Paw and continued through 1904. The second was started by A. L. Dacy under the direction of the author in 1911 in a 7-year-old orchard on the property of the Sleepy Creek Orchard Company, and the third was started in 1911 in a young orchard at Cherry Run, W. Va. The results of the three experiments are presented and discussed and a brief review is given of fertilizer experiments with peaches conducted at other stations.

In the earlier work in West Virginia better results were secured from complete fertilizers than from incomplete fertilizers. Of the separate elements, nitrogen gave the best results. Potash checked development and in some cases killed the trees and phosphoric acid exerted no influence on vigor or productivity.

The experiments at Sleepy Creek and Cherry Run were both conducted on a shale loam soil, low in fertility. In the Sleepy Creek test the yearly growth of trees treated with nitrate of soda has been double that of plats receiving no nitrogen. The bearing surface of nitrogen-fertilized trees was two and one-half times that of the nonnitrogen-fed trees at the end of the second year and there was a still greater difference at the end of the fourth year. The leaves of the nitrogen blocks were healthier and larger in size and about two and one-half times as numerous. The nitrogen plats set an average of 76 per cent fruit buds each year against 60 per cent on the nonnitrogen plats. The yield of fruit was nearly doubled by the use of nitrogen. The fruit was not so highly colored on the nitrogen blocks and maturity was delayed several days. The high color of the fruit on the nonnitrogen plats is attributed to the extra sunshine that

penetrated the sparse sickly foliage rather than to the influence of potash or any other fertilizer.

Nitrogen and potash in combination produced slightly larger fruit. The average gross income per acre from all nitrogen plats was \$468.85 and from the nonnitrogen plats \$275.43. The influence of lime appears to have been largely negative, although the production was somewhat increased.

In the experiment on young trees at Cherry Run, there was no appreciable influence of any fertilizer the first year. After the first year nitrogen produced a strong growth of wood and foliage while potash apparently weakened the vigor of the tree. Practically all of the small crop of fruit produced the fourth year was from nitrogen-fed trees.

The author concludes that the theory that heavy fertilizing with nitrogen is injurious to the peach is shattered by these experiments, as is also the former conception of the value of potash. Recommendations for shale and other soils low in fertility are 200 to 250 lbs. of nitrate of soda per acre for bearing trees and 0.5 lb. per tree for young trees after the first year. It is suggested that the necessary nitrogen may be advantageously supplied by means of leguminous cover crops, but this point has not been clearly demonstrated.

Experiments in fertilizing with catalytic substances of vine ash, S. CETTO-LINI (*Bol. Quind. Soc. Agr. Ital.*, 20 (1915), No. 13, pp. 431-438).—Data are given and discussed showing the effect on the quantity and composition of the must and wine of grapes fertilized with the following substances: Calcium sulphate, aluminium sulphate, magnesium sulphate, potassium permanganate, iron sulphate, sodium chlorid, and sulphur.

Citrus culture, W. J. ALLEN (*Dept. Agr. N. S. Wales Farmers' Bul.* 90 (1914), pp. 96, pls. 5, figs. 108).—A treatise on the culture, harvesting, marketing, and diseases of citrus fruits, with special reference to conditions in New South Wales.

The mangosteen, D. FAIRCHILD (*Jour. Heredity*, 6 (1915), No. 8, pp. 339-347, figs. 4).—A discussion of the mangosteen with reference to its distinguishing characteristics, edible qualities, and the possibility of its successful culture in tropical North America, together with notes on attempts to cultivate the mangosteen in other tropical countries and its adaptability for grafting on related species.

The palms of British India and Ceylon, indigenous and introduced, E. BLATTER (*Jour. Bombay Nat. Hist. Soc.*, 22 (1913), No. 3, pp. 444-463, pls. 8, fig. 1; 22 (1914), No. 4, pp. 665-681, pls. 7, fig. 1; 23 (1914), No. 2, pp. 269-281, pls. 5).—In continuation of previous articles (*E. S. R.*, 30, p. 444) a descriptive account is given of a number of additional native and introduced palms of British India and Ceylon.

Experiments in the germination of coffee carried out in Brazil, E. NAVARRO DE ANDRADE (*Fazendeiro, Sao Paulo*, 8 (1915), No. 1, pp. 3-8; *abs. in Internat. Inst. Agr.* [Rome], *Mo. Bul. Agr. Intel. and Plant Diseases*, 6 (1915), No. 5, pp. 710, 711).—The results are given of a comparative germination test of whole fruit, of seed without pulp, and of decorticated seed freed also from the parchment-like membrane. Generally speaking, the best germination was secured by planting whole fruits.

Tea culture in the Caspian Provinces of Persia and in Trans-Caucasian Russia, G. D. HOPE, trans. by C. BERNARD (*Dept. Landb., Nijv. en Handel [Dutch East Indies], Meded. Proefstat. Thee*, No. 36 (1915), pp. 27, pls. 2).—This comprises Dutch translations of descriptive accounts dealing with the culture and preparation of tea in the Caspian Provinces of Persia and Trans-Caucasian Russia.

Experiment to determine the most suitable distance apart for planting in nurseries, G. D. HOPE and H. R. COOPER (*Indian Tea Assoc., Sci. Dept. Quart. Jour., No. 2 (1915), pp. 36-38*).—The results of this experiment, which was conducted at the Tocklai Experimental Station, indicate that the width of planting tea seed best suited for nurseries is not less than 9 in. and not more than 12 in. Between these limits the choice would be dependent on the kind of seed and soil.

Suggestions for the manurial treatment of tea soils, G. D. HOPE and P. H. CARPENTER (*Indian Tea Assoc. [Pamphlet], 1915, pp. II+88, pl. 1*).—A discussion of the principles and practice of manuring tea, including a classification of the tea soils of Northeast India with special reference to their manurial treatment.

Experiment to determine the effect of lime on the growth of tea seedlings, G. D. HOPE and H. R. COOPER (*Indian Tea Assoc., Sci. Dept. Quart. Jour., No. 2 (1915), pp. 39, 40*).—In this experiment, which was conducted at the Tocklai Experimental Station, the soil was known to require lime. Both the check plat and limed plat were given cattle manure at the rate of 20 tons per acre, the limed plats receiving slaked lime containing 51 per cent calcium oxid at the rate of 1 ton per acre. As compared with the check plat there was a 49 per cent increase in weight of 100 plants, a 28 per cent increase in average height, and a 9 per cent increase in average circumference of the tea seedlings on the limed plat.

▲ **A summary of the investigations of Dr. P. van Romburgh, C. E. J. Lohmann, and Dr. A. W. Nanninga (1892-1906)**, J. J. B. DEUSS (*Dept. Landb., Nijv. en Handel [Dutch East Indies], Meded. Proefstat. Thee, No. 31 (1914), pp. 58*).—The investigations here summarized consist largely of chemical studies of the volatile products of fresh fermented tea, the content in caffeine and other alkaloids in different cultivated teas, fermentation and fertilization studies, investigations of changes taking place in the tea leaf, manufacturing tests, etc.

Medicinal plants and their cultivation in Canada, J. ADAMS (*Canada Expt. Farms Bul. 23, 2. ser. (1915), pp. 60, figs. 36*).—This bulletin deals with the medicinal properties of certain plants and discusses the possibility of growing these plants in certain parts of Canada. Consideration is given to soil, climate, and cultivation; collection and drying; imports and exports of medicinal plants; medicinal plants for which there is a considerable demand; medicinal plants used in moderate or small quantities; and foreign medicinal plants which might grow in Canada.

A bibliography dealing with the various medicinal plants is included. An appendix contains a note with reference to changes in medicinal plants made in the 1914 edition of the British Pharmacopœia.

Field book of western wild flowers, MARGARET ARMSTRONG (*New York and London: C. P. Putnam's Sons, 1915, pp. XX+596, pls. 48, figs. 500*).—A popular field book illustrating and describing a large number of the commoner wild flowers growing in Washington, Oregon, California, Idaho, Nevada, Utah, and Arizona. The flowers found only in the Rocky Mountains are not included. Attention is called to the fact that exceedingly few of the western flowers cross the Rockies and are found in the East.

New Zealand plants suitable for North American gardens, L. COCKAYNE (*Wellington: Govt., 1914, pp. 35*).—A descriptive list is given of evergreen and deciduous trees and shrubs, climbing plants, herbaceous and semiwoody plants, and ferns believed to be suitable for open air culture in the Pacific coast region, where there is little danger of severe frosts.

FORESTRY.

Annual report of the forestry bureau, C. R. PETTIS (*Ann. Rpt. Conserv. Com. N. Y.*, 4 (1914), pp. 65-179, pls. 15).—This comprises a report of the activities of the New York State Forestry Bureau for the fiscal year ended September 30, 1914. The report deals with the administration of the forest preserve, forest fire protective work, forest legislation, forest products, forest extension, and reforestation. Appended to the report is an account of a forest survey of a parcel of state land by A. B. Recknagel and B. H. Paul (pp. 119-137), and a report upon the resources of the forest preserve by C. R. Pettis (pp. 139-179).

Report of the director of forestry for the year 1914, R. H. CAMPBELL ET AL. (*Dept. Int. Canada, Rpt. Dir. Forestry, 1914*, pp. 133, figs. 29).—A report of the work of the forestry branch for the year 1913-14, to which are attached the reports of the officers in charge of the various subdivisions, including the tree-planting division, the forest reserves in the various Provinces, fire ranging, and the forest products laboratories of Canada. A report on wood bison is also included.

Annual report of the director of forestry of the Philippine Islands for the fiscal year ended December 31, 1914, W. F. SHERFESSEE (*Ann. Rpt. Dir. Forestry P. I., 1914*, pp. 78).—The usual progress report on the administration, investigation, and reconnaissance work in the Philippines for the fiscal year ended December 31, 1914.

Data showing applications for the homestead purchase and lease of the public lands, timber cut by species, revenues, timber licenses, utilization of forest products from public and private forests, exports and imports of forest products, etc., are appended.

Progress report of forest administration in the Andamans for the year 1913-14, J. L. BAKER (*Rpt. Forest Admin. Andamans, 1913-14*, pp. 3+VI+35, pl. 1).—This is the customary report on the administration of the state forests of the Andamans, including a financial statement for the year ended June 30, 1914. The more important data relative to forest areas, working plans, forest protection, miscellaneous work, revenues, yields, etc., are appended in tabular form.

Reforestation on the Black Hills National Forest, P. T. SMITH (*Ames Forester*, 3 (1915), pp. 5-9).—A summary of progress made in reforestation work on the Black Hills National Forest during the last ten years.

Range reconnaissance on the Wallowa National Forest, E. H. STEFFEN (*Ames Forester*, 3 (1915), pp. 10-28, pls. 2, figs. 2).—An account of the systematic examination and study of the range on the Wallowa National Forest.

The Abney hand level and the chain on intensive forest surveys, C. R. ANDERSON (*Forestry Quart.*, 13 (1915), No. 3, pp. 338-343).—The author calls attention to the poor results secured with the aneroid barometer in mapping on intensive surveys and gives directions and data for the use of the Abney hand level and the chain, which equipment has given rather general satisfaction in mapping forest surveys.

Rules of thumb for volume determination, F. R. MASON (*Forestry Quart.*, 13 (1915), No. 3, pp. 333-337).—The author here presents some rules of thumb for volume determination which are believed to be applicable for trees of various species.

A windfall problem, G. T. BAKER (*Forestry Quart.*, 13 (1915), No. 3, pp. 317-324, fig. 1).—The study here reported was conducted to ascertain if possible the cause of the considerable windfall occurring in the virgin woods on the Snow Creek watershed of the Olympic National Forest.

The results in general indicate that the danger of windfall is little affected by exposure or topography, except in the case of very steep exposed localities. Tall dominant trees with well-formed crowns are more liable to be wind-thrown than others. Much of the windfall among the shorter trees is due to opening up the stand or a disturbance of root systems by the falling of the larger trees.

A calendar of the leafing, flowering, and seeding of the common trees of the eastern United States, G. N. LAMB (*Mo. Weather Rev. Sup. 2 (1915), pp. 5-19, figs. 4*).—The preliminary chart or calendar here given has been formulated from data on the flowering, leafing, seed ripening, seed falling, and leaf falling of the common trees, which have been collected for a number of years, both by observers under the direction of the Forest Service and by individuals working alone.

The calendar includes some 72 species. In view of the lack of uniformity and incompleteness of observations in many cases, the chart is tentative in nature, but it is believed it will serve as a general guide to the seasonal functions of the different species. The use of the chart is explained and directions are given for making phenological observations, together with brief descriptions of the general range of each species.

A bibliography of literature used in compiling the chart is included.

The progress of wood identification in the Philippine Islands, E. E. SCHNEIDER (*Forestry Quart., 13 (1915), No. 3, pp. 325-332*).—A short review of investigations having to do with the identification of Philippine woods.

See data on some secondary tree species, E. A. ZIEGLER (*Forestry Quart., 13 (1915), No. 3, pp. 361-364*).—Data are given on some seed experiments carried on by A. B. Wells in the Pennsylvania State Forest Academy nursery in 1910 and 1911.

The maximum growth of Japanese timber species, S. HONDA (*Jour. Col. Agr. Imp. Univ. Tokyo, 6 (1915), No. 1, pp. 1-6, pls. 4*).—A list is given of Japanese trees according to their size and the largest existing specimen trees, together with tabular data showing the average maximum growth of some 49 species.

Loblolly or North Carolina pine, W. W. ASHE (*N. C. Geol. and Econ. Survey Bul. 24 (1915), pp. XVI+169, pls 27, figs. 5*).—A report on the loblolly or North Carolina pine (*Pinus taeda*), prepared under the direction of the North Carolina Geological and Economic Survey in cooperation with the Forest Service of the U. S. Department of Agriculture, with reference to its use by landowners, lumbermen, and others interested in timber.

The subject matter is presented under the following general headings: The tree and how to identify it, economic status of loblolly pine, physiography of the Coastal Plain and Piedmont Plateau regions, commercial distribution, associated species, forest characteristics, silvical requirements, the wood and its uses, commercial use for turpentine, growth, volume tables, graded volume tables, increase in the value of the trees, and management. Under forest management is taken up the determination of the best age at which to cut for saw timber or cordwood in order to utilize most profitably the forest crop. The best methods of cutting in order that the forests may be perpetuated are discussed for the different types. Protection from fire, especially for the young growth, is advocated and the advisability of artificial restocking by seeding or planting is considered.

Accompanying the text are over 80 tables presenting data on various phases of the subject.

Longleaf pine distinguished visually from loblolly or shortleaf, A. KOEHLER (*Engin. Rec., 72 (1915), No. 11, pp. 319, 320, figs. 5*).—A detailed study of the wood of longleaf, loblolly, and shortleaf pines, recently made at the

Forest Products Laboratory of the U. S. Department of Agriculture, has shown that the size of the pith in conjunction with the diameter of the second annual ring furnishes a reliable guide for determining the above species of wood without the aid of a microscope. This method of identification is described and a chart is given showing the relation of the pith diameter to the diameter of the second annual ring.

Strength tests of structural timbers treated by commercial wood-preserving processes, H. S. BETTS and J. A. NEWLIN (*U. S. Dept. Agr. Bul. 286 (1915), pp. 15, figs. 7*).—This bulletin describes experimental tests made by the Forest Service in cooperation with the Illinois Central Railway and one eastern and two western wood-preserving companies to determine how the strength of bridge stringers is affected by commercial creosote treatment. An account is given of the materials tested, methods of treatment, method of testing, and the results of tests. A bibliography of publications relating to strength tests of various woods is also given.

The tests have shown in general that timber may be very materially weakened by preservative processes, although creosote in itself does not appear to weaken the timber. A preservative process which may seriously injure one timber may have little or no effect on the strength of another. A fair comparison of the effect of a preservative process on the strength of different species can not be made unless it is the common or best adapted process for all the species compared. The same treatment given to a timber of a particular species may have a different effect upon different species of that species, depending upon the form of the timber used, its size, and its condition when treated.

The artificial preservation of mine timbers, F. MOLL (*Forestry Quart., 13 (1915), No. 3, pp. 308-316*).—An account of various European methods of preserving mine timbers, abstracted from the German by F. W. Haasis. See also a previous note (*E. S. R., 30, p. 647*).

Study on vegetable ivory, F. VIGNOLO-LUTATI (*Ann. R. Accad. Agr. Torino, 57 (1914), pp. 137-148, pl. 1*).—A short comparative study of vegetable ivory derived from different plants.

DISEASES OF PLANTS.

Annual report of the botanist and plant pathologist, F. STOWARD (*Dept. Agr. and Indus. West. Aust. Ann. Rpt. 1914, pp. 21-32*).—Sprain, a potato disease thought to be of physiological nature and not hereditary, appears to be accentuated by dry-soil conditions. *Heterodera radicola* has been discovered attacking potatoes for the first time in this region. Potato blight (*Phytophthora infestans*) reappeared after the lapse of a year, being reported from numerous points in several districts.

Premature shedding of blooms by tomato, which could not be associated with any organism, was ascribed to conditions of cultivation and season. Tomato wilt was almost invariably associated with *Fusarium* spp., which may constitute normally a portion of the fungus flora of the soil in this region. No case of tomato blight could be ascribed to *P. infestans*, and if such a disease is present it is thought to be rare.

Studies on cereals are briefly reported. Copper sulphate used alone for wheat smut was shown to cause loss, or more particularly abnormality in germination, in a large percentage of wheat seed tested.

Vine mildew (*Öidium tuckeri*) and anthracnose (*Glaeosporium ampelophagum*) were the most prevalent of the vine diseases noted. The former was controlled by several dressings of finely powdered sulphur, beginning as soon as the foliage is formed. The latter yielded to preventive treatment, a precaution

recommended being early destruction of all infected prunings. An unusual case of root rot may have been connected with a fungus rot of a neighboring fence.

Diseases of alfalfa included rust (*Uromyces striatus*), leaf spot (*Pseudoopezica medicaginis*), and European root disease (*Rhizoctonia medicaginis*), but none of these appears to amount to an epidemic.

The most common citrus disease was that due to *Armillaria mellea*, which is frequently traceable to residues of stumps or of other timber. A preliminary investigation of a rind disease of obscure origin has been commenced.

Studies with poisonous plants, seed investigations, etc., are also reported in this connection.

Mycology, F. J. F. SHAW (*Ann. Rpt. Bd. Sci. Advice India, 1913-14, pp. 99-105*).—This is largely a summary of material in articles most of which have already been noted from other sources. A note is also given on systematic mycology, with a list of articles published during 1913-14. Among the diseases dealt with are some affecting rice, sugar cane, palms, cotton, and sesame.

The more important plant enemies and their control, H. K. ANDERSEN (*De vigtigste Plantesygdomme og deres Bekæmpelse. Hasley, Denmark: R. Torkildsens Bogtr. 1913, pp. 82, figs. 49*).—Some common diseases and disorders of cultivated plants are discussed, with control measures appropriate thereto, after which some animal enemies of economic plants are discussed on the same general plan.

The control of plant diseases in Sweden, J. ERIKSSON (*Internat. Inst. Agr. [Rome], Mo. Bul. Agr. Intel. and Plant Diseases, 5 (1914), No. 12, pp. 1546-1553*).—This is a brief review of researches, publications, and other steps taken looking to the control of plant diseases in Sweden since the beginning of work in 1876, also an account of the appearance, progress, and effects of some important diseases in that country. Among these are American gooseberry mildew (*Sphaerotheca mors-uvæ*), which appeared in 1905 and is now present in most of the Swedish gardens; potato canker (*Synchytrium endobioticum* or *Chrysophlyctis endobiotica*), observed in 1912 and soon brought under control; about a dozen rusts named of cultivated cereals or of allied grasses, also other kinds of rusts, as those on white pine and on hollyhock, and other plant diseases, as *Monilia fructigena* and *M. cinera* on fruit trees, and *Podosphaera leucotrieha*, causing apple mildew. Mention is also made of articles reporting investigations on various diseases. Recent efforts for the establishment of international collaboration for the control of plant diseases are also noted, but it is thought that the most important diseases causing about 90 per cent of the annual losses can not be advantageously controlled by legislative measures.

Some work of official botanical institutions is also briefly noted.

Mercury chlorophenol as a fungicide, T. REMY and J. VASTERS (*Illus. Landw. Ztg., 34 (1914), Nos. 91, pp. 769-771; 92, pp. 776-778, fig. 1*).—A report is given of tests employing low percentages of mercury chlorophenol, a commercial preparation, against certain plant diseases.

In case of stinking smut of wheat it appears to be safe and at least as effective as others in use. Results with wheat and barley treated for loose smut were less conclusive, but no injury resulted from its use, and the same facts are noted in regard to oats treated for low germinability. Leaf spot of peas, while not entirely prevented, was lessened by this treatment. *Glæosporium lindemuthianum* on garden beans was decreased without injury to the crop. Beet rot was decreased by treatment of the seed balls. Seed treatment of barley reduced leaf stripe. The remedy appears especially beneficial in treating a combination of stinking smut, Fusarium, and leaf stripe of grains.

Infection experiments with parasitic fungi, IV, O. TREBOUX (*Ann. Mycol.*, 12 (1914), No. 5, pp. 480-483).—This is a continuation of studies previously noted (E. S. R., 28, p. 844) regarding the habits and tendencies of several rust fungi in connection with host plants.

The 1914 outbreak of rust on winter grain in Bavaria, L. HILTNER (*Wechnbl. Landw. Ver. Bayern*, 1914, No. 25; *abs. in Internat. Inst. Agr. [Rome]*, *Mo. Bul. Agr. Intcl. and Plant Diseases*, 5 (1914), No. 8, p. 1091).—In parts of Bavaria alarm was caused by rust on wheat and rye, due generally to *Puccinia glumarum*, occasionally associated with *P. triticeina*. The features of the outbreak are compared with those of a previous one.

It is thought that the rust is less severe on fields properly manured, also on those having a good even stand as compared with those having a thin stand.

The true cause of severe outbreaks is held to be the weather, the outbreak occurring after a number of hot days followed by frosts or heavy dews and cool weather. Local quick-growing varieties were most severely attacked, other varieties, especially pedigreed ones, remaining nearly free. Mist seems very favorable to the spread of rust. The first reports of attack came from the same place each year, confirming, it is held, the importance of atmospheric factors.

The cause and prevention of dry spot of oats, W. KRÜGER and G. WIMMER (*Ztschr. Ver. Deut. Zuckcrindus.*, No. 704 (1914), II, pp. 707-758, pl. 1, figs. 12).—A description is given of this trouble, with an account of an extended study thereon. It is claimed to be primarily physiological, due to the injurious influence of residues of physiologically alkaline salts (in particular sodium nitrate), and avoidable by altering the character of the soil as regards alkalinity. This may have been increased in soils at first only slightly alkaline by reactions occurring in connection with commercial fertilizers employed, calcium carbonate being significant in this connection.

Suggestions made regarding the treatment of excessively limy soils include the employment of iron chlorid, iron sulphate, or powdered sulphur, and the use of green manure crops or stable manure.

Experimental studies on the causes predisposing wheat to attack by Erysiphe graminis, V. RIVERA (*Ricerche Sperimentali sulle Cause Predisponenti il Frumento alla "Nebbia."* Rome: *R. Staz. Patol. Veg.*, 1915, pp. 42, figs. 4).—An account is given of studies on the germinability of the conidia of *E. graminis* and the receptivity of wheat plants for the fungus as influenced by various factors.

It is stated that a condition predisposing the host to attack is diminution of turgor, which may be due to dryness of the soil or to elevation of the temperature of the air. Germination of the conidia, on the other hand, is favored by a state of moderate humidity and temperature. These facts may help to explain the contradictions in the claims made by investigators. The question of susceptibility may reduce itself to a consideration of the relation between cellular turgor in case of the fungus and epidermal tension on the part of the host. The constitution of the cell sap and membranes as determined by nutritional supply may be a further factor.

A bibliography is appended.

A new disease of germinating wheat, P. J. O'GARA (*Science*, n. ser., 42 (1915), No. 1079, pp. 313, 314).—The author reports having observed considerable unevenness of the stand in Utah wheat fields in April, 1915, there being a large proportion of very weak plants. The fields were known to have been infested in the previous year by the wheat straw worm, but a careful examination of the infected plants did not reveal the presence of the larvæ of this insect.

An examination of the plants in the laboratory showed that the wheat kernels were infected with a fungus which is believed to be an undescribed species of *Podosporiella*, a description of which is promised later.

A new alfalfa leaf spot in America, L. E. MELCHERS (*Science, n. ser., 42* (1915), No. 1085, pp. 536, 537).—The author reports having observed in the vicinity of Manhattan, Kans., alfalfa plants which were not producing a normal amount of foliage, the stems being sparsely set with spotted leaves, which were affected with a singular leaf spot. The diseased plants all presented an unthrifty appearance and were also somewhat smaller than normal.

The spots, which were generally circular or elliptical, were scattered irregularly over the entire surface, frequently occurring along the margins. During the earliest stages the spots were small and dark reddish-brown. They soon increased in size and had a dark-brown margin bounding the ashen-gray center. The diseased tissue did not fall out and the leaves remained intact. The spots were confined almost exclusively to the leaflets, but they have been observed on the petioles.

Material has been studied in the laboratory, and experiments show the pathogenicity of the fungus, which is said to belong to the genus *Pleosphæruina*. The species has not been definitely determined.

Treatment of beet seed for control of root scab, W. KRÜGER and G. WIMMER (*Ztschr. Ver. Deut. Zuckerindus., No. 705* (1914), II, pp. 845-847).—Comparative tests with several fungicidal preparations for prevention of root scab showed little or no protective value except in case of carbolic acid of 0.5 per cent strength, which reduced attack to 5 or 10 per cent of the whole number of plants.

Celery diseases (*Inst. Phytopath. Wageningen, Vlugschr. 9* (1914), pp. 3).—Leaf spot (*Septoria apii*) is reported as widely prevalent. An effective seed treatment is 0.25 per cent formalin. Only soil free from infection should be used, and Bordeaux mixture is advised if the disease appears on the plants.

The same seed treatment is applicable to rust or scab (*Phoma apicicola*). Seed beds on infected soil require treatment with strong formalin.

A bacterial rot for which no effective treatment is yet available is also noted on ground having deficient drainage.

Diseases of crucifers (*Inst. Phytopath. Wageningen, Vlugschr. 10* (1914), pp. 4, fig. 1).—Finger-and-toe of crucifers (*Plasmiodiophora brassicæ*) is controlled by repeated applications of lime. Notes are given on *Phoma oleracea*, which is controlled by measures effective as against the cabbage fly (*Anthomyia brassicæ*), carrying the infection, also on *P. apicicola*, which is controlled by treating the seed and seed bed with formalin.

Root nodosities of crosses between swedes and turnips, L. HEDWEG (*Internat. Inst. Agr. [Rome], Mo. Bul. Agr. Intel. and Plant Diseases, 5* (1914), No. 7, pp. 833-836, pls. 4).—This is a short account of information obtained in Denmark in researches on crosses between swedes and turnips and the nodosities occurring on their roots. These nodosities, which are of various forms according as the hybrid in question is rape-like, swede-like, or turnip-like, are described separately, and their characters are contrasted with those of the finger-and-toe swellings caused by *Plasmiodiophora brassicæ*.

It is claimed that the constancy of the Danish strains of swedes and turnips resulting from years of selection may now be considered as thoroughly established.

Peppermint rust, B. GRÓF (*Kisérlet. Közlem., 17* (1914), No. 4, pp. 657-661, figs. 2).—The phases of attack by *Puccinia menthæ* on Japanese peppermint are described.

Collection and destruction of all fallen leaves in autumn and spraying with 2 per cent copper sulphate are recommended, as are also repetition of the spraying in early spring and removal of the crop early in June before development of the uredo stage is complete.

Potato diseases, E. HENNING (*Kort översikt öfver riktigare smittosamma sjukdomar hos potatisen*. Stockholm: Wilhelmssons Boktr., 1915, pp. 28, figs. 8).—A brief discussion is given of *Hypochnus solani*, *Phytophthora infestans*, *Synchytrium endobioticum*, *Spongospora scabica*, *Fusarium*, and such disorders as bacterial ring rot, scurf, and leaf roll.

Potato diseases (*Bol. Agr. Téc. y Econ.*, 6 (1914), No. 71, pp. 1031-1040).—This is a brief discussion of direct and contributory local causes of potato diseases or disorders, including fungi, bacteria, and nematodes, also of some protective measures as used in certain localities.

Blight resistance in potatoes, W. S. HILL (*Jour. Agr. [New Zeal.]*, 8 (1914), No. 4, pp. 370, 371, fig. 1; *abs. in Internat. Inst. Agr. [Rome], Mo. Bul. Agr. Intel. and Plant Diseases*, 5 (1914), No. 8, p. 1088).—The author notes comparative experiments showing the superiority of the variety Gamekeeper over Up-to-date, as regards resistance to late blight. He also discusses briefly some other qualities.

Fusaria of potatoes, C. D. SHERBAKOFF (*New York Cornell Sta. Mem.* 6 (1915), pp. 87-270, pls. 7, figs. 51).—The results of a monographic study begun in 1911 of the species of *Fusarium* found on the potato are given. In this work the fungi were studied in their *Fusarium* stages, no attempt being made to determine their perfect forms. All the cultures were made from diseased parts of the potato plant received from nearly every experiment station in the United States, most of them isolated from tubers affected with dry or soft rots.

In all the author recognizes 61 species and varieties of *Fusarium*, and in addition he gives descriptions of 3 species of *Ramularia* which are said to be often found on the potato and easily confused with species of *Fusarium*. The following new species and varieties are technically described: *F. cuneiforme*, *F. udum solani*, *F. falcatum fuscum*, *F. caudatum solani*, *F. metacroum minus*, *F. subulatum brevius*, *F. effusum*, *F. truncatum*, *F. lucidum*, *F. diversisporum*, *F. biforme*, *F. anguioides*, *F. anguioides caudatum*, *F. arthrosporioides*, *F. arthrosporioides asporotrichius*, *F. sporotrichioides*, *F. arcuosporum*, *F. ferruginosum*, *F. sanguineum*, *F. sanguineum pallidum*, *F. bullatum*, *F. bullatum roseum*, *F. angustum*, *F. redolens solani*, *F. lutulatum*, *F. lutulatum zonatum*, *F. sclerotioides*, *F. sclerotioides brevius*, *F. oxysporum asclerotium*, *F. oxysporum longius*, *F. oxysporum resupinatum*, *F. subpallidum*, *F. subpallidum roseum*, *F. claratum*, *F. discolor triscriptatum*, *F. culmorum letcius*, *F. martii viride*, *F. martii minus*, *F. solani cyanum*, *F. solani suffuscum*, *F. striatum*, and *R. solani*.

In connection with the investigation, the author made some studies on environmental conditions and also the pathogenicity of the fungi. Extensive inoculations of potato plants with all the *Fusaria* described in the memoir yielded negative results, and would indicate that they are not wilt producers. Several series of inoculations of potato tubers showed that a considerable number of species of *Fusarium* can cause more or less rapid decay of the tubers, but that most of the species reported upon produced rot only after the tubers had begun to sprout. The most common rot-producing organism, at least in the eastern United States, is claimed to be *F. caeruleum*. The inoculation experiments carried on with tubers seem to indicate that some species of the fungi, while differing morphologically, may act very similarly so far as their pathological conditions are concerned, and that others closely related from the morphological standpoint differ widely in their pathogenicity.

The transmission of potato mosaic through the tuber, E. J. WORTLEY (*Science, n. ser.*, 42 (1915), No. 1083, pp. 460, 461).—The author states that the mosaic disease of potato is very prevalent in Bermuda on the variety Bliss Triumph, the yield of affected plants being reduced from 10 to 75 per cent.

An inspection of the fields on Long Island in which stock was being grown for shipment to Bermuda for seed purposes showed the general presence of mosaic on this variety. The same conditions existed in Maine, where stock for Long Island had been obtained.

Tubers from healthy and mosaic plants were obtained in Maine and later planted in Bermuda, with the result that diseased plants were produced through planting tubers from mosaic parent plants. The yield was greatly reduced due to the presence of the disease, but the experiments indicate that the trouble may be controlled by field selection of stock intended for planting.

It is believed that these experiments are the first to show definitely that the potato mosaic disease is transmitted through the tubers.

Powdery scab of potatoes in Oregon, F. D. BAILEY (*Science, n. ser.*, 42 (1915), No. 1082, pp. 424, 425).—The occurrence of potato scab due to *Spongospora subterranea* is reported. The lot of potatoes in which the disease was first found is said to have been raised on a farm in the isolated district of Tillamook County, Oreg., where, according to the grower's statement, seed of the variety was introduced from an eastern State some 12 or 15 years ago, and no seed had been introduced since that time. A hasty survey of the county did not show the presence of the disease on any other farm, but one diseased specimen was discovered at a store from which there was no possibility of tracing it to the grower.

The fact that the district is isolated and that potatoes are not raised in sufficient quantity for export is believed to be the reason why the disease has not been more generally disseminated.

Wart disease of potatoes, J. ERIKSSON (*Internat. Inst. Agr. [Rome], Mo. Bul. Agr. Intel. and Plant Diseases*, 5 (1914), No. 2, pp. 276-278).—Inquiry and research in England since 1909 have shown that black scab of potato, caused by *Chrysophlyctis endobiotica* (*Synchytrium endobioticum*), tends to spread slowly but steadily, the organism retaining its virulence in the soil for years and resisting all the ordinary fungicides but affecting different varieties of potato unequally. Common English varieties are divided into three groups with reference to the resistance that they have shown to this disease. The formalin treatment tested recently in Sweden has already been noted. (E. S. R., 31, p. 842).

Withering of the panicle in rice, P. POLI (*Gior. Riscicolt.*, 4 (1914), No. 14 pp. 206-209, figs. 2; *abs. in Internat. Inst. Agr. [Rome], Mo. Bul. Agr. Intel. and Plant Diseases*, 5 (1914), No. 10, p. 1365).—Colatura, a disease of rice, is described. It consists in a form of abortion of some flowers, which reduces the yield. Certain Japanese varieties are more resistant than those native to Italy. The disease is said to be entirely distinct from a somewhat similar injury to the emerging panicle, which is caused by hail.

As the result of researches carried out in different seasons, the disease is considered due to excessive fertility combined with a period of intense cold during the last phase of flower formation, while the panicle is still inclosed.

A disease affecting the sisal hemp plant, C. K. BANCROFT (*Jour. Bd. Agr. Brit. Guiana*, 7 (1914), No. 4, pp. 181, 182; *abs. in Internat. Inst. Agr. [Rome], Mo. Bul. Agr. Intel. and Plant Diseases*, 5 (1914), No. 9, pp. 1246, 1247).—Examination of material collected locally has confirmed the conclusions of Shaw (E. S. R., 29, p. 246) regarding the identity and mode of attack of the

organism, *Colletotrichum agaves*, which is shown to be a wound parasite on the sisal plant in British Guiana since 1908 or earlier.

The disease affects first the older leaves, frequently near the tips, spreading to young leaves and finally to all parts of the plant and to neighboring plants, and causing the appearance of yellow patches.

Careful supervision with immediate destruction of affected leaves and the application of such fungicides as Bordeaux mixture are suggested.

Leaf spot disease of sisal in German East Africa, K. BRAUN (*Pflanzer*, 10 (1914) No. 4, pp. 188-197, pl. 1; *abs. in Internat. Inst. Agr. [Rome], Mo. Bul. Agr. Intcl. and Plant Diseases*, 5 (1914), No. 8, p. 1085).—A leaf spot disease of sisal, which has been noted previously (*E. S. R.*, 20, p. 155), was more than usually noticeable in 1913. Investigations have shown that this appearance, which is described, may be produced experimentally by even short exposures to temperatures which frequently occur in this region in summer. It is not known whether other unfavorable factors may not increase the susceptibility of the plant in this respect.

Occurrence of the bacterial disease of Sudan grass in the Salt Lake Valley, Utah, P. J. O'GARA (*Science, n. ser.*, 42 (1915), No. 1079, pp. 314, 315).—It is claimed that a bacterial disease of Sudan grass has been recently observed in Utah. The specimens exhibited elongated reddish-brown blotches on the leaves, many of the lower leaves being entirely dead. On the under surface of the spots were found characteristic reddish crusts or scabs consisting of dry bacterial ooze, which had come from the interior of the leaves. An examination showed the presence of bacteria, and the author thinks there is little doubt that the disease is due to the broom corn bacterial organism (*Bacillus sorghi*) first studied by Burrill, whose conclusions were later confirmed by Kellerman and Swingle.^a

Diseases and enemies of sugar beets and alternating crops in Bohemia, H. UZEL (*Ztschr. Zuckerrindus. Böhmen*, 38 (1914), No. 11, pp. 571-578).—This is a condensed report, dealing with nematodes and other animal parasites of sugar beets, with the leaf fungi *Sporidesmium putrefaciens*, *Phyllosticta beta*, and *Cercospora beticola*, and with such bacteria as those causing root rot and scab.

As regards alternating crops notes are given of *Tilletia tritici* on wheat, *Urocystis occulta* on rye, *Ustilago jenseni* on barley, and *Phytophthora infestans* on potato.

Control of beet nematodes, H. C. MÜLLER and E. MOLZ (*Ztschr. Ver. Deut. Zuckerrindus.*, No. 707, 1914, II, pp. 959-1050, figs. 3).—This is an account of studies bearing upon the control of *Heterodera schachtii* in relation to sugar beets, including experiments with chemical, physical, and other means.

Both potassium carbonate and sodium carbonate seemed to favor an increased nematode attack. Results were not favorable to the use of sulphur or sodium chlorid. Carbon bisulphid at 3 cm. depth in the soil gave better results than at 20 cm. Formaldehyde gave as good results with employment of a smaller quantity. Allyl alcohol was effective whether used pure or diluted with water. Several other treatments increased more or less the severity of attack. A modification of the Kühn method of trap plants is recommended.

Nematodes were found in the greatest numbers at 10 to 20 cm. below the surface, few or none being found at 50 to 60 cm. depth. The vertical or horizontal distribution of nematodes introduced into sterile soil was comparatively slow under experimental conditions.

Sugar cane gummosis, J. GROENEWEGE (*Meded. Proefstat. Java-Suikerrindus.*, 5 (1915), No. 3, pp. 29-124, pls. 7; *Arch. Suikerrindus. Nederland. Indië*, 23

^a U. S. Dept. Agr., Office Expt. Stas. Bul. 2, pt. 2, p. 34.

(1915), No. 7, pp. 189-284, pls. 7).—This is an extended study of *Bacterium vascularum* in its causative relation with gummosis of sugar cane, which is described in connection with associated factors and conditions. A bibliography is appended.

The new disease or dry disease of the sugar cane, C. K. BANCROFT (*Jour. Bd. Agr. Brit. Guiana*, 7 (1914), No. 4, pp. 183-187; *abs. in Internat. Inst. Agr. [Rome]*, *Mo. Bul. Agr. Intel. and Plant Diseases*, 5 (1914), No. 9, p. 1247).—The symptoms, progress, and effects of this disease are described. It is said to have been observed first in this colony in 1907, but to have spread since that time to estates elsewhere, its progress being apparently slow and its tenure uncertain in some localities.

Investigations have borne out the conclusions of Stockdale (E. S. R., 32, p. 441) inasmuch as *Marasimus sacchari* was found in what was probably a causal connection with the disease. It is said to be propagated by spores, underground mycelium, diseased cuttings, etc.

Control measures include drainage and cultivation for increased vigor, abandonment of ratooning, change of crops, isolation by means of trenches, sanitary measures (as the employment of lime), and the use of resistant varieties named.

Occurrence of *Thielavia basicola* as a root parasite of watermelons in the Salt Lake Valley, Utah, P. J. O'GARA (*Science*, n. ser., 42 (1915), No. 1079, p. 314).—The author reports having observed *T. basicola* parasitic on roots of watermelons. He believes that this is the first case in which it has been found as an active parasite in any part of the United States west of the Mississippi River.

Bitter pit, its cause and cure, D. McALPINE (*Fruit World Austral.*, 15 (1914), Nos. 5, pp. 143-153, figs. 21; 6, pp. 179-187, figs. 10; 7, pp. 215-222, figs. 7).—A summary is given of the second report on the bitter pit of apples (E. S. R., 31, p. 244), dealing principally with the cause of bitter pit, factors that contribute to its development, and methods for its control.

Fluctuating conditions of temperature and humidity are said to be the principal contributing factors in the development of this disease. There is also said to be a distinct relation between the system of pruning and the prevalence of bitter pit. The transpiration of the fruit as affected by various factors, such as pruning, manuring, cultivation, etc., is discussed at length.

The control of bitter pit in the growing fruit, D. McALPINE (*Prog. Rpt. Bitter Pit Invest. [Aust.]*, 3 (1913-14), pp. 176, pls. 43).—This is the third progress report on bitter pit (see above). The investigation, which is still in progress, has now been extended to influences of many kinds affecting the trees and the fruit both before and after it is gathered, as related to bitter pit injury. The question as to whether bitter pit originates only while the fruit is yet on the tree is still unsettled.

It has been found that the increase of transpiration in the growing fruit is referable to the increase of its transpiring surface and the decrease in humidity of the air at this season of the year in this region. Fruit borne on laterals remained free from the disease even when the rest of the fruit on the tree was badly pitted.

Biochemical tests of growing fruit and X-ray studies of stored apples are being made to determine the inception and developmental conditions of bitter pit. It has been established that an excessive flow of sap toward the fruit causes a tendency to pit. This is lessened or neutralized by checking the sap flow, for which purpose constriction is being tested. Severe cutting back for grafting purposes resulted in one case in the pitting of 92 per cent of the apples borne on the remaining branches, while neighboring trees on which only

the leaders were shortened, the laterals being left untouched, showed no bitter pit of the ordinary type.

At a temperature of 31 to 32° F. in storage, the development of bitter pit and the ripening process were both arrested.

Canker of fruit trees (*Inst. Phytopath. Wageningen, Vlugschr. 13 (1914), pp. 4*).—*Nectria ditissima* is discussed as a wound parasite of fruit trees (apple and pear), also of several forest trees, into which it finds entrance only at points of injury from hail, insects, etc. It is controlled by the employment of tree surgery after the cankers have developed, fungicidal sprays, as Bordeaux mixture, being of use only to prevent development from the spore stage.

The conditions determining the outbreak of vine mildew in Hungary, G. VON ISTVANFFI (*Internat. Inst. Agr. [Rome], Mo. Bul. Agr. Intel. and Plant Diseases, 5 (1914), No. 9, pp. 1242-1245*).—A summary is given of studies on downy mildew conducted by F. Sávoły under the author's direction, and published in the fifth volume of the publications of the Royal Hungarian Central Ampelological Institute of Budapest.

It is believed that adequate study of the climatic conditions favorable to mildew will require investigations covering an extensive and varied territory for several years. Satisfactory results require a study of the weather before the first appearance of the mildew, at least as regards temperature and quantity and frequency of rainfall. Curves called isophanes have been mapped connecting points of simultaneous appearance of the disease. The successive isophanic belts between these show an increase in breadth, each being about 1.55 times as wide as the preceding one.

During 1910 to 1912 the earliest appearance in Hungary was on May 21, most appearances being between June 5 and 15 during the flowering period of the vines, and the infection occurring especially within the last ten days of May. Comparison of the mildew maps during four years shows that the mildew occurs in the same locality each year, and its spread follows usually the same routes, this constancy depending more upon orographic and soil relations than upon weather. The mildew generally proceeded more or less continuously from one locality to another, the speed being unequal in different directions, but the same in given directions every year.

The mildew starts from a definite area described as of triangular form, and advances for a time in approximately the direction of the angles. Independently of this first area, and one or two isophanes later, secondary centers are observed, one of which becomes the point of departure of an independent invasion.

The temperature of the month of April appears to have an influence on the outbreak of mildew. Regularity of temperature changes (with sufficient moisture in winter and spring) favors its early appearance, but repeated relapses in the normal rise of temperature may bring about a retardation of the appearance, both frequency and duration of the temperature relapses being apparently influential in this regard.

An attempt has been made to obtain and express in an equation a "bios" or biological value of the weather as related to mildew outbreak, and the calculated and actual appearance dates as given herein from 1910 to 1913 show a fair degree of correspondence, especially in case of the inner isophanes. A chief condition of complete success for the method is a network of stations in telegraphic communication.

According to these researches the districts in which mildew makes its first appearance in Hungary are determined by orographic and climatic conditions and especially by the nature of the soil and of the conditions of superficial

hydrography. The weather influences only the date of the appearance. The disease appears first not in regions of greatest warmth and heaviest rainfall, but in those of extensive sandy areas and tracts liable to flooding. The disease appears later, however, on cold soils, despite abundance of superficial water and favorable weather. After an April with regular temperature and without white frosts the first outbreak occurs about May 15.

Resistance of hybrid direct-bearer vines to mildew, E. PÉE-LABY (*Vie Agr. et Rurale*, 3 (1914), No. 22, pp. 603-605; *abs. in Internat. Inst. Agr. [Rome], Mo. Bul. Agr. Intel. and Plant Diseases*, 5 (1914), No. 7, p. 962).—Lists are given, based upon tests made, of grape hybrids which require for safety in moderate mildew years no spraying with copper sulphate. Mention is made of other desirable hybrids not yet conclusively tested but probably resistant to mildew.

Rose diseases (*Inst. Phytopath. Wageningen, Vlugsch. 12* (1914), pp. 1-3).—In addition to some animal parasites, mildew (*Sphaerotheca pannosa*), rust (*Phragmidium subcorticium*), and false mildew (*Peronospora sparsa*) of rose are discussed, with treatments as recommended.

Field studies on the dissemination and growth of the chestnut blight fungus, P. J. ANDERSON and D. C. BABCOCK (*Penn. Chestnut Tree Blight Com. Bul.* 3 (1912), pp. 45, pls. 14).—This report refers to work carried out chiefly at Charter Oak and Mt. Gretna, Pa.

Tests for infection gave positive results in all but three of eleven kinds of wounds. Inoculation of natural insect holes in no case to date produced a canker, but it is believed that any wound in the bark may furnish an entrance for the fungus.

Among the known or suspected means of dissemination are nursery shipments, grafts, shipments of timber and fire wood (moisture and shade assisting), dead leaves, burs, bark, tools, wind, and rain. The agency of birds has not been established. Ants may possibly carry the spores. Experiments indicate that a beetle (*Leptostylus maculata*) eats the spores, and that it may be really beneficial.

The fungus grows much more rapidly in dead than in living tissue. Spores are very long lived and quickly become active upon being wetted. Conidia can produce infection after being kept dry in the spore-horn stage for 19 weeks. The greatest rate of spread in the cankered spots was obtained during July and August.

A fungus, in all outward appearance the same as *Endothia parasitica*, is reported on *Quercus velutina*, *Q. alba*, *Q. prinus*, *Rhus typhina*, *Acer rubrum*, and *Carya oratu*, and it was isolated from all but *Q. prinus*. The chestnut blight fungus was repeatedly grown on sterilized twigs of all of the above and on *Castanea dentata*, *Q. macrocarpa*, *Q. rubra*, *Q. coccinea*, *Nyssa sylvatica*, *Liriodendron tulipifera*, and *Juglans nigra*, producing pycnidia regardless of the mode of inoculation. The growth on all oaks, on sour gum, and on sumac was as rapid and vigorous as on chestnut twigs. The fungus appears to be a weak parasite on white oak, chestnut oak, and sumac.

The anatomical and physiological conditions of chestnut branches attacked by the ink disease, L. PETRI (*Atti R. Accad. Lincei, Rend. Cl. Sci. Fis., Mat. e Nat.*, 5. ser., 23 (1914), I, No. 5, pp. 363-369; *abs. in Internat. Inst. Agr. [Rome], Mo. Bul. Agr. Intel. and Plant Diseases*, 5 (1914), No. 7, p. 964).—The author has followed up previous observations on the part played by *Coryneum modonium* in producing black canker of chestnut (E. S. R., 29, p. 156; 30, p. 52).

In branches three to nine years old collected at the end of November, 1913, various differences were found between the healthy and the diseased branches. It seems that the earliest and most serious irregularity takes place in the min-

eral food, the destruction of chlorophyll and the disorganization of the chloroplasts in the cortical parenchyma being probably the consequences of assimilatory disturbances and reduced protoplasmic vitality, connected with high acidity, absence or reduction of calcium oxalate, and increase of gallic acid, these conditions permitting attack by weak parasites some time before any diseased condition is apparent.

Forest botany, R. N. PARKER (*Ann. Rpt. Bd. Sci. Advice India, 1913-14*, pp. 95-98).—Besides brief notes regarding the progress of work on floras in preparation and lists of recent papers on forest botany, the results are given, so far as obtained, from a study of the wood of *Pinus excelsa* attacked by *Trametes pini*.

Mycelium was present in heartwood and in sapwood next to the cambium, while this was to all appearances sound. Trees apparently sound showed, on microscopical examination, the presence of hyphæ in the tracheids and the medullary rays. Roots, both small and large, also contained mycelium in wood otherwise free from rot. In case of natural root grafts, fungal hyphæ were found in the grafted roots on both sides of the union, this fact showing the possibility of infection in this manner. The fungus appeared to cause little or no rot except in the heartwood of the stem and larger roots.

ECONOMIC ZOOLOGY—ENTOMOLOGY.

Economic entomology in the United States of America, I. V. EMEL'ANOV (*Selskokhoziâistvennaïa Entomologiâ v Soedinennykh Shtatakh Sîvernoï Ameriki. Petrograd: Govt., 1914*, pp. 275, pls. 3, figs. 128; rev. in *Rev. Appl. Ent.*, 3 (1915), Ser. A, No. 1, p. 42).—A report upon economic entomology in this country, based upon the author's visits during 1910-11 and 1912.

Some present needs in economic entomology, H. T. FERNALD (*Jour. Econ. Ent.*, 8 (1915), No. 1, pp. 30-40).—In this paper the author points out some important phases of economic entomology that need investigation.

A new air-conditioning apparatus, G. A. DEAN and R. K. NABOURS (*Jour. Econ. Ent.*, 8 (1915), No. 1, pp. 107-113, pls. 3, fig. 1).—The authors here describe the general arrangement, principle of operation, and moisture and temperature records maintained in the breeding chamber by an air-conditioning machine which has been manufactured for and installed at the Kansas Experiment Station.

Cages and methods of studying underground insects, J. J. DAVIS (*Jour. Econ. Ent.*, 8 (1915), No. 1, pp. 135-139, pls. 3).—The author here describes and illustrates the methods made use of in investigations carried on by agents of the Bureau of Entomology of this Department.

The conditions of the resistance of internal parasitic insects in the organism of their hosts, W. R. THOMPSON (*Compt. Rend. Soc. Biol. [Paris]*, 77 (1915), No. 23, pp. 562-564; abs. in *Rev. Appl. Ent.*, 3 (1915), Ser. A, No. 5, pp. 251, 252).—It is pointed out that the resistance offered by internal parasitic larvæ, both dipterous and hymenopterous, to the toxic and digestive diastases which the author here discusses is an aspect of the adaptation of parasite to host which entomologists appear to have hitherto neglected.

The toxicity of insecticides, C. W. WOODWORTH (*Science, n. ser.*, 41 (1915), No. 1053, pp. 367-369).—The author describes the methods employed in determining the effect of hydrocyanic acid gas on scale insect eggs in closed glass containers. The results of one series of tests with the European fruit scale on Christmas berry are presented in tabular form.

Some recent insect importations into New Jersey, H. B. WEISS (*Jour. Econ. Ent.*, 8 (1915), No. 1, pp. 133-135).—The author describes briefly the discovery

of numerous important insect pests from abroad which have been intercepted during the course of inspection work in New Jersey.

A review of the spread in Russia of the chief injurious animals in 1913, I. A. PORTCHINSKY (*Ezheg. Dept. Zeml. [Russia], 1913, pp. 14, figs. 4; abs. in Rev. Appl. Ent., 3 (1915), Ser. A, No. 3, pp. 111, 112*).—Notes on the more important pests of the year.

[Philippine insects] (*Philippine Jour. Sci., Sect. D, 9 (1914), No. 5, pp. 409-464, pls. 2, figs. 11*).—The papers here presented deal with Studies in Philippine Jassoidea: I. Some Remarkable Tettigoniellidae, by C. F. Baker (pp. 409-421); Philippine Histeridae, by H. Bickhardt (pp. 423-431); New Fulgoridae of the Philippines, II, by L. Melichar (pp. 433-439); Elateridae of the Philippine Islands, by E. Fleutiaux (pp. 441-449); Catalogue of the Pselaphidae (Coleoptera) of the Philippine Islands, by A. Raffray (pp. 451-455); and New Philippine Hymenoptera, by J. C. Crawford (pp. 457-464).

Annual report of the officer in charge of the insectary for the year ended June 30, 1914, L. J. NEWMAN (*Dept. Agr. and Indus. West. Aust. Ann. Rpt. 1914, pp. 60-66*).—An account is here given of the occurrence of and work with the more important insects of the year.

Division of entomology, annual report, 1913-14, C. P. LOUNSBURY (*Union So. Africa Dept. Agr. Rpt., 1913-14, pp. 199-216*).—This, the usual annual report (E. S. R., 31, p. 548), deals with the work of the year, including nursery and port inspection; the work with locusts, to which a considerable part of the report is devoted; investigations by the Cape entomologist, C. W. Mally; wattle insect investigations, by C. B. Hardenberg; etc.

The enemies of the Jerusalem artichoke, P. NOEL (*Bul. Trimest. Lab. Ent. Agr. Seine-Infér., No. 3 (1914), pp. 15, 16; abs. in Rev. Appl. Ent., 3 (1915), Ser. A, No. 1, p. 33*).—A list of the more important artichoke pests.

The principal enemies of rice in Indo-China, L. DUPONT (*Jour. Agr. Trop., 14 (1914), No. 157, pp. 204-207; abs. in Internat. Inst. Agr. [Rome], Mo. Bul. Agr. Intel. and Plant Diseases, 5 (1914), No. 10, pp. 1380, 1381*).—Among the more important insects mentioned are *Sesamia inferens*, *Schœnobius bipunctiferus*, *Cnaphalocrocis medinalis*, *Artona walkeri*, *Sitotroga cerealella*, and *Leptocoris varicornis*.

A short text-book on the control of insect pests of orchards, S. TSESHEVSKAGO (*Kratkoe Rukovodstvo po Bor'bie s Vreditel'jami Plodovago Sada iz Klassa Nasit'ekomykh. Petrograd: Imp. Russ. Obshch. Plodovodstva, 1914, pp. 44, figs. 61; rev. in Rev. Appl. Ent., 3 (1915), Ser. A, No. 4, p. 183*).—A popular handbook arranged by seasons for the use of orchardists in Russia.

Insects and man, C. A. EALAND (*New York: The Century Co., 1915, pp. 343, pls. 68*).—An account of the more important harmful and beneficial insects, their habits and life histories, etc. The subject is dealt with under the headings of insects and plants, insects and human disease, insect enemies of live stock, beneficial insects, household insects, some human parasites, and insect control. A classified bibliography covering ten pages, and subject and authorities indexes are included.

A preliminary list of insects which have wilt, with a comparative study of their polyhedra, J. W. CHAPMAN and R. W. GLASER (*Jour. Econ. Ent., 8 (1915), No. 1, pp. 140-149, fig. 1*).—The summary and conclusions drawn from the investigations here reported are as follows:

“Wilt occurs in many widely different species of insects. The clinical aspects of wilt are very similar in all the species of caterpillars studied by us. Wilt first appears in a chronic form, as conditions become more unfavorable it becomes acute, and finally terminates in a general epidemic. There is a striking similarity in shape between the polyhedra of the different species of

caterpillars given in Group A. The polyhedra in the different species vary greatly in size. The great difference in size which exists between polyhedra in the same caterpillar tends to strengthen our view that the polyhedra are reaction bodies."

A bibliography of 11 titles is included.

An illustrated catalogue of American insect galls, M. T. THOMPSON (*Nassau, N. Y.: Rhode Island Hospital Trust Co., 1915, pp. 72, pls. 21*).—The first part (pp. 5–46) of this posthumous work consists of a catalogue of the gall-making Cynipidae of North America, with the classification arranged by galls and by genera, and includes a bibliography of species descriptions (pp. 47–49). A supplemental list of American gall-making insects (pp. 50–66), and an index to the genera and species are included.

The first part of this catalogue is published practically as left by the late author, while the second part, or supplemental catalogue, was assembled from his original notes by the author's father, the late S. M. Thompson, who is also responsible for the selection and grouping of the illustrations on the plates. The numerous plates, consisting of 246 separate figures, reproduce photographs of galls taken by the late author. The work as a whole is edited by E. P. Felt.

The transmission of exanthematous typhus to man and monkey by lice, E. SERGENT, H. FOLEY, and C. VIALATTE (*Compt. Rend. Acad. Sci. [Paris], 158 (1914), No. 13, pp. 964, 965*).—This is a report of results obtained during the course of experiments with recurrent fever conducted in Algeria, in continuation of those previously noted (E. S. R., 24, p. 82).

The authors call attention to the fact that Nicolle and his collaborators (E. S. R., 22, p. 552) succeeded in four cases in transmitting exanthematous typhus in monkeys through the bites of infected lice, and that Ricketts and Wilder (E. S. R., 23, p. 559) have furnished indirect proof of this rôle of lice. The authors' experiments confirm the above-mentioned results. They show that exanthematous typhus may be transmitted to man through the bite of adult infected lice and that lice taken from an individual thus infected may in turn transmit the disease to monkeys. In addition it was found that the infection acquired by a louse is hereditary and that individuals arising from eggs laid by an infected louse may transmit the disease.

The application of iron sulphate in orchards (*Sad, Ogorod i Bakhcha, No. 5 (1914), pp. 307, 308; abs. in Rev. Appl. Ent., 2 (1914), Ser. A, No. 8, pp. 515, 516*).—The application of iron sulphate is recommended to destroy moss and lichens on trees and as a remedy for *Psylla mali*. A 3 per cent solution should be applied before the buds swell, but since it does not destroy all the eggs of this psyllid, a further spray consisting of 0.5 or 0.75 lb. of tobacco extract in 11 qt. of water immediately after the larvæ have hatched is recommended.

Notes on some Colorado aphids having alternate food habits, C. P. GILLETTE and L. C. BRAGG (*Jour. Econ. Ent., 8 (1915), No. 1, pp. 97–103*).—Notes are here presented on 31 species, among which mention may be made of *Chermes cooleyi*, *Pemphigus betæ*, *Schizoneura americana*, *S. rileyi*, *S. cratægi*, *S. lanigera*, etc.

The brown grape aphid, A. C. BAKER and W. F. TURNER (*Science, n. ser., 41 (1915), No. 1066, p. 834*).—The authors report upon observations at Vienna, Va., of the life cycle of *Macrosiphum viticola*. The eggs are deposited in the axils of leaves of *Viburnum prunifolium* in late October or November and the young hatch out in the spring before the leaves open and feed on the bursting flower buds. The second generation matures late in April or in early May and nearly all become alate. The alate forms are unable to subsist on *Viburnum* and migrate to the grape where they produce a third generation and

where the species lives throughout the summer, producing apterous and alate forms.

The emergence from the soil of the first young of the grape phylloxera in Italy, B. GRASSI (*Atti. R. Accad. Lincei, Rend. Cl. Sci. Fis., Mat. e Nat.*, 5. ser., 23 (1914), II, No. 2, pp. 19-30; *abs. in Internat. Inst. Agr. [Rome], Mo. Bul. Agr. Intel. and Plant Diseases*, 5 (1914), No. 10, p. 1377).—The emergence of the young from the soil is more or less abundant throughout the year, except during hibernation and the period preceding the birth of the first daughter generation of the hibernating females. In southern Italy they do not appear so frequently from the second half of July to the end of August, the period corresponding with the partial estivation of the insect.

The use of the fungus *Isaria* for the control of the black scale, H. J. QUAYLE and A. R. TYLOR (*Mo. Bul. Com. Hort. Cal.*, 4 (1915), No. 7, pp. 333-338, figs. 2).—The experiments here outlined and the general observations made in the groves treated have been summarized by the authors as follows:

"The *Isaria* fungus growing under suitable conditions in a moist chamber, either in the laboratory or the field, was found to kill a fair percentage of the black scale. The results in attempting to disseminate the fungus artificially under natural conditions in the field, at least at the season indicated, have been wholly negative. From observations made in the various groves where the fungus has been disseminated commercially, there is absolutely no evidence, thus far, to show that the fungus has been of any importance whatever in checking the scales. Where natural conditions are favorable for the development of the fungus, as in the district contiguous to the coast in Santa Barbara County, the *Isaria* will kill more or less of the black scale, but the field where it would thrive can not be greatly enlarged, if at all, by attempts at artificial dissemination. From our recent experiments and observations as well as general observations made on this fungus since 1908, the writers feel justified in extending to citrus growers no hope that this fungus will keep their trees free from the black scale."

Scurfy scale on Norway maple (*Leucaspis japonica*), E. P. FELT (*Jour. Econ. Ent.*, 8 (1915), No. 1, p. 160).—The author records a severe infestation of the twigs and leaves of Norway maple and privet at Stamford, Conn., by *L. japonica*.

The crisis in Italian sericulture and the measures for averting it, O. BORDIGA (*Internat. Inst. Agr. [Rome], Mo. Bul. Agr. Intel. and Plant Diseases*, 5 (1914), No. 10, pp. 1263-1270).—A discussion of the conditions that have brought about a crisis in sericulture in Italy.

State moth work, plan and progress of work, 1913-14, W. C. O'KANE (*N. H. Dept. Agr., State Moth Work Circ. 6 [1915], pp. 22, pls. 7*).—A report of the status of the work carried on in New Hampshire.

On the biology of *Bupalus piniarius* and some of its parasites, V. PLOTNIKOV (*Reprint from Rev. Russe Ent.*, 14 (1914), No. 1, pp. 21, figs. 8; *abs. in Rev. Appl. Ent.*, 3 (1915), Ser. A, No. 1, pp. 48, 49).—The author reports that among 372 caterpillars examined, 14 per cent were infested with *Campoplex*, 12 per cent with *Lydella nigripes*, 4 per cent with both of the above-mentioned parasites, and 2 per cent with *Platylabus cothurnatus*.

A mechanical protector for preventing injury by the peach borer, E. B. BLAKESLEE (*Jour. Econ. Ent.*, 8 (1915), No. 1, pp. 103-107).—This abstract of a paper presented at the annual meeting of the American Association of Economic Entomologists describes a cone-shaped tarred paper protector which, when placed at the crown of the tree, forms an impenetrable barrier, and not only prevents the deposition of eggs at that point but prevents the larvæ from working downward on the trunk and attacking the crown. When an impenetrable

barrier was placed at the crown of the tree, the larvæ made no attempt to enter above it.

Experiments with lime-sulphur spray against the larch moth (*Coleophora laricella*), I. TRÄGÅRDH (*Centralanst. Jordbruksförsök Flygbl. 49 (1914), pp. 3; abs. in Rev. Appl. Ent., 3 (1915), Ser. A, No. 4, p. 191*).—The author's experiments confirm the results obtained by Herrick (E. S. R., 28, p. 857), showing that lime-sulphur spray is an excellent remedy for the larch moth.

The burdock gelechiid, an insect seed destroyer, A. GIBSON (*Ottawa Nat., 28 (1914), No. 7, p. 96; abs. in Rev. Appl. Ent., 3 (1915), Ser. A, No. 2, p. 72*).—The author reports that nearly every seed head of the lesser burdock (*Arctium minus*) in the Ottawa district is found to harbor one or more larvæ of *Metzneria lappella* through the autumn and winter. In this way the lepidopteran becomes a useful insect. So abundant has the insect become that it is the exception to find a seed head in which the small caterpillar is not wintering.

Fumigation for the box leaf miner, E. P. FELT (*Jour. Econ. Ent., 8 (1915), No. 1, pp. 94-96*).—A brief report of experiments with *Monarthropalpus bursi*, which has become well established on Long Island, where it is seriously injuring ornamental box hedges.

Preliminary experiments indicate that fumigation with one teaspoonful of carbon bisulphid to 5 qt. of space for a period of at least one hour will kill the larvæ without injury to the plant. Tests of carbon tetrachlorid, C. P. ammonia, and naphthalin flakes were made with less favorable results. Fumigation for 15 minutes with potassium cyanid at the rate of 1 dram to 27 cu. ft. of space or about one-half the strength recommended for fumigating nursery stock destroyed some of the larvæ and did not injure the foliage.

A caterpillar (*Oria muscosa*) injuring grain crops and methods of combating it, N. VITKOVSKY (*Abs. in Rev. Appl. Ent., 2 (1914), Ser. A, No. 12, p. 712*).—A popular account of this most serious pest of grain crops in south Russia and means for its control. In one district in the Province of Dou 2,700 acres of crops were damaged, of which 810 acres were totally destroyed.

The question of fighting *Oria muscosa*, A. O. FABRIKANT (*Zeml. Ghoz., No. 35 (1914), pp. 1137, 1138; abs. in Rev. Appl. Ent., 3 (1915), Ser. A, No. 1, p. 15*).—The author reviews the work of a special conference on the control of *O. (Tapinostola) muscosa*. During 1912 its damage to crops in the Government of Ekaterinoslaf amounted to as high as \$1,289,622.50, as many as 54,000 acres of crops being totally destroyed and 67,000 acres damaged in only five districts of the Government.

***Oria muscosa* in the Government of Ekaterinoslaf according to the data for 1914.—Distribution, biology, and method of control**, N. N. VITKOVSKY (*Abs. in Rev. Appl. Ent., 3 (1915), Ser. A, No. 3, pp. 110, 111*).—An account of the life history of this noctuid which was the source of considerable injury during 1914. See also notes above.

***Mycodiplosis magregori* n. sp.**, E. P. FELT (*Jour. Econ. Ent., 8 (1915); No. 1, p. 149*).—This itonidid was reared from red spider on cotton at Batesburg, S. C.

Malaria in the Philippine Islands.—I, Experiments on the transmission of malaria with *Anopheles (Myzomyia) febrifer* sp. nov., *A. (Pseudomyzomyia) rossii*, *A. (Myzorhynchus) barbirostris*, *A. (Myzorhynchus) sinensis*, and *A. (Nyssorhynchus) maculatus*, E. L. WALKER and M. A. BARBER (*Philippine Jour. Sci., Sect. B, 9 (1914), No. 5, pp. 381-439*).—The authors' experiments show that among the anopheline mosquitoes in the Philippine Islands *A. febrifer* is probably the most susceptible to infection with the parasites of subtertian malaria, and while the number of experiments with tertian and quartan malaria is insufficient to determine the fact, it is probable that this species is also an efficient carrier of these types of the disease. "This species is from

three to four times as susceptible as *A. rossii*, which has hitherto been considered the malaria carrier of the Philippines, and eleven times as susceptible as *A. barbirostris*. The number of mosquitoes of the species *A. sinensis* and *A. maculatus* dissected, especially in the comparative experiments, is too small to give reliable percentages. It is possible that a larger series of experiments with *A. sinensis* would show that this species can be infected. . . .

"The rôle played by a species of Anopheles in the transmission of malaria in any country depends chiefly upon (1) its susceptibility and (2) its geographical distribution and prevalence; also, to some extent, upon (3) its avidity for human blood and (4) its domesticity."

A list of 21 references to the literature is included.

On the life history of the pipunculids, intracœlomic parasites of *Typhlocyba*, D. KEILIN and W. THOMPSON (*Compt. Rend. Soc. Biol. [Paris]*, 78 (1915), No. 1, pp. 9-12, figs. 11; *abs. in Rev. Appl. Ent.*, 3 (1915), Ser. A, No. 5, p. 252).—It is pointed out that, aside from the discovery by Boheman in 1854 of the parasitism of cicadellids by a pipunculid larva, the discovery by Giard in 1889 of the parasitism of *Typhlocyba* by *Atelenevra spuria*, and the fact that they usually oviposit in the bodies of Homoptera and may be employed in controlling some species injurious to plants, such as sugar cane, very little is known of their bionomics.

The authors report upon studies of *Typhlocyba rosea*, *T. hippocastani*, and *T. douglasi* attacked by *A. spuria* and what is thought to be another pipunculid.

A new *Sarcophaga* parasitic on *Allorhina nitida*, J. M. ALDRICH (*Jour. Econ. Ent.*, 8 (1915), No. 1, pp. 151, 152, fig. 1).—A new dipteran reared from pupæ of *A. nitida* in Virginia, Indiana, Illinois, Michigan, Georgia, Florida, and Louisiana is described as *Sarcophaga utilis*.

Notes on certain points of economic importance in the biology of the house fly, F. C. BISHOPP, W. E. DOVE, and D. C. PARMAN (*Jour. Econ. Ent.*, 8 (1915), No. 1, pp. 54-71).—This report of studies of the biology of the house fly conducted in Texas includes tables which show in detail the preoviposition period, developmental periods, and longevity of the house fly at Dallas.

Note on the use of poisoned bait for controlling the house fly (*Musca domestica*), C. W. MALLY (*So. African Jour. Sci.*, 11 (1915), No. 9, pp. 321-328).—The author concludes that from the standpoint of expense the poison bait method is very much cheaper than any other that has come to his attention.

The effect of temperature on the life cycle of *Musca domestica* and *Culex pipiens*, S. D. KRAMER (*Science, n. ser.*, 41 (1915), No. 1067, pp. 874-877).—The results of studies of the average duration of the egg, larval, and pupal stages of the house fly at 20, 30, and 35° C. are presented in tabular form, as are studies of the immature stages of mosquitoes (*C. pipiens*) at 20°, room temperature, and 30°.

The celery fly (*Acidia heraclei*), J. FEYTAUD (*Bul. Soc. Étude et Vulg. Zool. Agr.*, 13 (1914), No. 7, pp. 109-114, figs. 2; *abs. in Rev. Appl. Ent.*, 3 (1915), Ser. A, No. 4, p. 188).—This dipteran is a source of injury to celery in southwest France through its mining in the leaves.

A new species of Ulidiinae from Tucuman, J. BRÈTHES (*Bul. Soc. Ent. France*, No. 2 (1914), pp. 87, 88, fig. 1).—The new dipteran here described as *Euxesta chavannei* is said to cause the decomposition of the young shoots of the sugar cane, and the canes are then invaded by *Bacillus sacchari* which causes a disease known as "polvillo."

[*Cycloneda (Neda) sanguinea*, an important coccinellid in Brazil], F. IGLESIAS (*Chacaras e Quintaes*, 10 (1914), No. 6, pp. 434, 435, figs. 3; *abs. in Rev. Appl. Ent.*, 3 (1915), Ser. A, No. 4, p. 169).—A brief account of a coccinellid

which is of considerable importance through its clearing oranges and rose trees of aphids in Brazil.

Life history of *Oberea tripunctata*, A. G. RUGGLES (*Jour. Econ. Ent.*, 8 (1915), No. 1, pp. 79-85, figs. 6).—The beetle here considered has become a pest in the parks of St. Paul, Minn. In June, 1911, all the trees along one of the finest avenues of that city were found by the author with numerous dead leaves hanging from the terminal twigs and the ground strewn with leaves. Studies have since been made of its life history and are here reported.

The eggs are inserted under the edge of the slit bark of twigs, below the completed girdles, many often being found in a single stem, although all between the complete girdling next the main stem and the end of the twig soon perish. Five larval instars have been observed and are here described. Pupæ were found only in the second year after the eggs, usually in May. It was estimated that in 1911-12 from 50 to 80 per cent of the larvæ were parasitized. The cutting out and burning of infested twigs was recommended and appears to have given satisfactory results in the control of this borer.

On the life history of *Aleochara bilineata*, a staphylinid parasite of *Chortophila brassicæ*, J. T. WADSWORTH (*Jour. Econ. Biol.*, 10 (1915), No. 1-2, pp. 1-27, pls. 2, fig. 1).—An account is here given of the life history of a staphylinid beetle, the larvæ of which parasitize the pupæ of the cabbage root fly (*C. brassicæ*), including technical descriptions of its stages.

"It is shown that the larvæ of this insect hatch from the ova in the form of typical, free-living, campodeiform, staphylinid larvæ. They enter the puparia of the cabbage fly, feed on the pupæ contained therein, and at the first ecdysis emerge as eruciform larvæ. They thus undergo a simple form of hypermetamorphosis as the result of their parasitic mode of life. Three ecdyses occur during larval life. Previous observers believed that ova or larvæ of the beetle enter the fly larvæ; this view, however, is shown to be erroneous. After the first ecdysis the larvæ feed rapidly; pupation takes place within the puparium of the host, and the adult beetle, after gnawing a hole in the wall of the puparium, emerges therefrom.

"Two generations of these staphylinids are produced annually in the Manchester district, and it is suggested that in warmer climates three or more generations may be produced in a year. Adults of the first generation emerge in May and June; as larvæ they entered the host puparia in late autumn of the previous year. Apparently eight or nine months elapse while the individuals of this generation undergo their metamorphoses. Adults of the second generation emerge from the host puparia in August and September. Six or seven weeks only are occupied by this generation in completing the developmental cycle. The rate of development of larvæ obtained in winter may be greatly increased by placing them in warm surroundings. Adults, which would normally emerge in May or June, may be thus obtained in midwinter. It is suggested that other members of the genus *Aleochara* will be found to have similar life histories, possibly with modifications. It is also probable that the larvæ of *A. bilineata* parasitize other dipterous hosts than *C. brassicæ*.

"Two hundred and thirty-nine cabbage fly puparia infested by staphylinid larvæ were obtained from 2,189 puparia examined, equivalent to 10.9 per cent. The puparia collected during the summer months showed a higher percentage of parasites, viz, 26.9 per cent. It is estimated that at least 20 per cent of the larvæ and pupæ of *C. brassicæ* are destroyed by coleopterous and hymenopterous parasites in the district where the material for this investigation was obtained.

"In view of the marked destructiveness of the cabbage fly and of the fact that practical methods of reducing it in numbers do not appear yet to have

been devised, it is suggested that the increase in numbers and utilization of its natural enemies is worthy of consideration."

A bibliography of 21 titles is included.

Notes on some hymenopterous parasites bred from the pupæ of *Chortophila brassicæ* and *Acidia heraclei*, J. T. WADSWORTH (*Ann. Appl. Biol.*, 2 (1915), No. 2-3, pp. 158-161).—During the course of an investigation of the life histories of parasites which attack soil insects, and particularly of the life history of a staphylinid (*Alcochara bilineata*) the larvæ of which attack the pupæ of the cabbage root fly (*C. brassicæ*), the author reared *Phygadeuon fumator*, *Atractodes tenebricosus*, and *Cothonaspis (Eucoila) rapæ* from pupæ of *C. brassicæ*, and *Hemiteles crassicornis* and *Adelura apii* from pupæ of the celery fly (*A. heraclei*).

A simple record system for apiary inspection, W. E. BRITTON (*Jour. Econ. Ent.*, 8 (1915), No. 1, pp. 121-123).—The author describes a system that has been used in Connecticut.

The spotted fever tick (*Dermacentor venustus*) and its control in the Bitter Root Valley, Montana—a review, R. A. COOLEY (*Jour. Econ. Ent.*, 8 (1915), No. 1, pp. 47-54).—A review of the Rocky Mountain spotted fever situation in Montana, including control work now under way and a summary of the biology of the spotted fever tick.

Some insect flagellates introduced into vertebrates, H. B. FANTHAM and ANNIE PORTER (*Proc. Cambridge Phil. Soc.*, 18 (1915), No. 2, pp. 39-50, pl. 1).—The investigations here reported have led to the following conclusions:

"Insect flagellates, e. g., *Herpetomonas jaculum* from *Nepa cinerea* and *H. ctenocephali* parasitic in the dog flea, *Ctenocephalus canis*, can live inside certain vertebrates (e. g., mouse and dog, respectively) and can multiply therein. This we have shown experimentally.

"If such flagellates be inoculated intraperitoneally or are fed by the mouth in food, the flagellates can find their way into the blood stream and internal organs (e. g., liver, spleen, bone marrow) of the vertebrate host. The insect flagellates are pathogenic to the vertebrates experimented upon, producing symptoms like those of leishmaniasis (kala-azar). The oval post-flagellate forms appear to be more capable of developing in vertebrate hosts than are other stages of the herpetomonad parasite of the insect. It may be expected that the various leishmaniases, occurring in different parts of the world, will prove to be insect-borne herpetomoniasis."

A list of 15 references is included.

Further experimental researches on insect flagellates introduced into vertebrates, H. B. FANTHAM and ANNIE PORTER (*Proc. Cambridge Phil. Soc.*, 18 (1915), No. 3, pp. 137-148).—"Herpetomoniasis can be induced in various warm- and cold-blooded vertebrates when the latter are inoculated or fed with herpetomonads occurring in the digestive tract of various insects. The infection produced and the protozoal parasites found in the vertebrates resemble those of human and canine leishmaniases. An infection can also be induced in certain vertebrates when they are fed or inoculated with *Crithidia gerridis*, and both flagellate and nonflagellate stages occur therein, but no transition to a trypanosome was found.

"The following Flagellata have proved pathogenic to warm-blooded mammals when the latter have been fed, or inoculated subcutaneously or intraperitoneally with them: *Herpetomonas jaculum*, *H. stratiomyæ*, *H. pediculi*, and *C. gerridis*. The hosts used were mice of various ages. That *H. ctenocephali* can infect dogs has already been shown by us. *H. jaculum* and *C. gerridis* have also been successfully fed or inoculated into cold-blooded hosts, namely, fishes

(*Gastrosticus aculeatus*), frogs, toads, lizards (*Lacerta vivipara*), and grass snakes (*Tropidonotus natrix*).

"As we have previously stated we believe that leishmaniasis are arthropod-borne herpetomoniasis, and that these maladies have been evolved from flagellates of invertebrates (especially herpetomonads of insects), which have been able to adopt themselves to life in vertebrates.

"In areas where leishmaniasis are endemic, an examination should be made of all insects and other invertebrates likely to come into contact with men or dogs or rats and mice, in order to ascertain if these invertebrates harbor herpetomonads. Preventive measures should be directed against such invertebrates, especially arthropods. Further, it is likely that certain vertebrates, such as reptiles and amphibia (especially those that are insectivorous), may serve as reservoirs for leishmaniasis or, as they should preferably be termed, herpetomoniasis. From such reservoirs the herpetomonads may reach man by the agency of ectoparasites or flies, especially such as are sanguivorous."

A list of 18 references is included.

Parasites of the American muskrat (*Fiber zibethicus*), F. D. BARKER (*Jour. Parasitology*, 1 (1915), No. 4, pp. 184-197, pls. 2, figs. 4).—In continuation of work previously noted (E. S. R., 29, p. 484), the author describes a number of new parasites, including 8 trematodes, 2 cestodes, and 3 nematodes.

Sarcosporidia encountered in Panama, S. T. DARLING (*Jour. Parasitology*, 1 (1915), No. 3, pp. 113-120, pls. 4).—During the routine examination of nearly 1,000 animals, sporidia were detected in three new hosts—namely, the opossum, hawk, and sloth.

Larval trematodes from North American fresh water snails, W. W. CORT (*Jour. Parasitology*, 1 (1914), No. 2, pp. 65-84, figs. 15).—This is a preliminary report which deals with 14 new cercariæ found in 6 species of fresh-water snails obtained from 7 localities. A list of 8 references to the literature is included.

Some North American larval trematodes, W. W. CORT (*Ill. Biol. Monographs*, 1 (1915), No. 4, pp. 86, pls. 8).—It is pointed out that practically nothing is known of the life history of the trematodes of North America, and even in Europe, where many new adults are being described each year, only a few developmental cycles are completely known. A list of references given of literature on larval trematodes from North American molluscs includes but 11 species. The present paper adds 14 new species of cercariæ from North American fresh-water snails. A preliminary report, taking up briefly the structure and activity of these cercariæ, is noted above.

A bibliography of 36 titles is included.

Trematode parasites and the relationships and distribution of their hosts, S. J. JOHNSTON (*Rpt. Austral. Assoc. Adv. Sci.*, 14 (1913), pp. 272-278).—This paper is based upon studies conducted by the author in Australia.

Studies on the cestode family Anoplocephalidæ, H. DOUTHITT (*Ill. Biol. Monographs*, 1 (1915), No. 3, pp. 96, pls. 6).—A comparative anatomical study of this family, including a key to the known species and descriptions of 8 new species.

"The cestodes of the subfamily Anoplocephalidæ are in some way dependent upon rich soils for their existence, and they thrive best in wet lowlands. The evidence points to the conclusion that the intermediate hosts are some group of insects which is confined to such regions; and since the hosts of the Anoplocephalidæ are almost exclusively herbivorous, it would seem as if this host were a small, plant-feeding insect."

A four-page bibliography is included.

Tænia saginata.—A case presenting structural abnormalities and associated with spurious parasitism in an infant, M. C. HALL (*Jour. Amer. Med. Assoc.*, 64 (1915), No. 24, pp. 1972, 1973, fig. 1).—The author records the occurrence of the unarmed or beef tapeworm in a child said to be from 14 to 18 months old.

FOODS—HUMAN NUTRITION.

The feeding of school children, MILDRED BULKLEY (*London: G. Bell & Sons, Ltd.*, 1914, pp. XVI+278).—This book is based upon a study, carried out in the year 1913, of the practical workings of the Act of Parliament of 1906 providing for the use of public funds, under certain restrictions, for the serving of meals in schools.

Owing to discretionary powers vested in local authorities marked differences were found in the spirit with which the work was carried on in different districts, as well as in the method of supervision, the selection of beneficiaries, the time and place of serving meals, and the wholesomeness of the food provided. As a result of the investigation, the author suggests that the act should make it obligatory to provide for underfed children; that meals should not be discontinued during holidays; that the half-penny limit should be removed; that the meals should be a part of the regular school system; and that they should be so prepared and served as to be of educational value. In rural schools, where, as a rule, the number of children is small, the serving of meals should be combined with the teaching of home economics.

The book considers the history of the movement for the provision of school meals, the extent and causes of malnutrition, and the effect of school meals upon the children and upon the parents. An appendix contains sample menus and information regarding the provision of meals in Scotland and abroad, this information being based on a review of the literature.

Economy in food during war, A. K. CHALMERS (*Lancet [London]*, 1915, II, No. 10, pp. 561-564).—Several ways in which economy in the use of food may be secured are considered.

Sprouted wheat, R. HARCOURT (*Canad. Miller and Cerealist*, 7 (1915), No. 10, pp. 239, 246).—The author reports baking tests to determine the usefulness of the sprouted wheat which resulted from the warm, wet weather at harvest time. His work indicates that a wheat containing 10 per cent of slightly sprouted grain may still produce a flour that will make good bread. Slightly sprouted grain is defined as that in which the sprout is from $\frac{1}{4}$ to $\frac{1}{2}$ the length of the kernel. Badly sprouted wheats are considered practically useless for milling purposes.

Commercial value of flour, B. R. JACOBS (*Canad. Miller and Cerealist*, 7 (1915), No. 10, pp. 245, 246).—A score-card system is described by which the commercial value of flour may be computed. Moisture, ash, gluten quality, acidity, color value, loaves per barrel, fermentation value, loaf volume, loaf color and texture, and the length of the fermentation period are the factors upon which the ratings are based.

Better breads by means of natural lactic acid, A. WAHL (*Jour. Indus. and Engin. Chem.*, 7 (1915), No. 9, pp. 773-775).—A preliminary report of an investigation of the quality of bread as influenced by the addition to the dough of lactic acid produced by *Bacillus delbruecki* (an organism found in germinated barley). The results of the investigation may be summarized briefly as follows:

The addition of bacterial lactic acid to the dough resulted in an improved general appearance of the loaf and a larger loaf per weight of bread. The bloom and color of the crust were improved and a greater whiteness of crumb

resulted, with better texture, "consisting of a more uniform distribution of the fermentation gas cells which are of smaller size in augmented number, with avoidance of large holes, thus eliminating crumbliness and producing a more velvety crumb. . . .

"Finer flavor and increased palatableness in the bread by virtue of a chemical combination with the phosphates of the flour" resulted.

"By using bacterial lactic acid produced by propagating *B. delbruecki* in a bran mash, all the highly nutritious extractive substances of the bran are thus incorporated into the dough, while the lactic acid renders soluble the proteins and basic phosphates of the flour, which results in a more wholesome product by reason of its increased digestibility."

It is stated that "the 'microbi-cidal' tendencies of lactic acid check the growth of those undesirable micro-organisms which tend to cause a disagreeable taste, bad odor, ropiness, and other bread diseases.

"Bacterial lactic acid extracts of malted cereals at low temperatures contain in addition the activated proteolytic and diastatic enzymes, peptase, and diastase, which act during dough fermentation to effect a partial digestion of the dough, the resulting soluble proteins, phosphates, and carbohydrates serving as a most desirable nourishment for the yeast.

"Milk, whey, buttermilk, and similar milk products containing either added or developed bacterial lactic acid, when added to the dough, also effect a similar improvement in the bread.

"Commercial lactic acid may be used with improved results, but bacterial lactic acid is preferable, and that bacterial lactic acid which is produced by the organism *B. delbruecki* is the most desirable, since this lactic acid with the extractive substances in it contains a much greater concentration of hydrogen ions upon which the effectiveness of this acid largely depends."

Westphalian blood bread, O. RAMMSTEDT (*Ztschr. Angew. Chem.*, 28 (1915), No. 38, Aufsatzteil, pp. 236-238).—Analytical data are given showing the chemical composition of rye, wheat, and army breads, and Westphalian blood bread, which is prepared with the addition of blood obtained from slaughterhouses to increase the nutritive value of the bread and to save in the amount of flour used.

Blood bread, R. KOBERT (*Chem. Ztg.*, 39 (1915), No. 12, p. 69).—The author advocates the addition of 10 per cent of the blood of slaughtered animals to all flour used in bread making during the war, as this blood contains nearly 13 per cent of protein, some lecithin and cholesterol, and valuable inorganic salts. Bread prepared in this way, when freshly baked, has an agreeable taste. The danger from infectious diseases is held to be negligible, as any bacteria present are killed by the baking process.

Decision of the German Imperial Health Bureau on the use of potato products in bread (*Arb. K. Gesundheitsamt.*, 48 (1915), No. 4, pp. 595-606).—Baking experiments are described in which various proportions of potato starch, potato flakes, and whole potato flour were used in admixture with rye flour and baked in the usual way. The bread was subsequently analyzed to determine principally the amounts of water and total nitrogen present.

The total energy value of the potato bread was found to be only inconsiderably less than that of pure rye bread. The products containing as much as 20 per cent of potato flour were judged not inferior to rye bread in general appearance, color, odor, and taste.

The protein content of the potato bread is held to be the only quantity that varies considerably from that of pure rye bread, but when 20 per cent of potato starch or flour is used in the bread the percentage of protein present is much smaller than when only 5 per cent is used. It is maintained that sufficient

protein from other sources is supplied by the ordinary mixed diet, of which either pure rye or potato flour forms only a part. While the amount of water contained in the bread may be increased by the use of potatoes, this factor is easily regulated. The proportions of potato products recommended for use are equal parts of flakes and starch, or of the whole potato flour and starch.

The use of sugar beets for food, HERZFELD (*Deut. Zuckerindus.*, 39 (1914), No. 43, pp. 885, 886).—In studying methods of preparing sugar beets for human food, the author conducted experiments to reduce the excessive sweetness, to produce an easily digestible product, and to overcome the disagreeable flavor. The method recommended is as follows: Cut the beets into small pieces (size of a hazelnut), cover with water, add 1 gm. of crystallized sodium carbonate for each 100 gm. of beets, and boil from 20 to 30 minutes. (This treatment is said to soften the beets and to remove the biting taste.) Finally pour off half the water and acidify with vinegar.

Chemical examination of ghee, K. H. VAKIL (*Jour. Soc. Chem. Indus.*, 34 (1915), No. 7, p. 320).—The author defines Indian ghee as a form of clarified butter obtained from cow's milk or from buffalo's milk. Analytical data regarding a number of samples are given.

Heather tea, a substitute for black tea (*Schweiz. Apoth. Ztg.*, 53 (1915), No. 12, pp. 173, 174).—It is noted that the flowering sprigs of *Calluna vulgaris* furnish a passable substitute for black tea, the infusion having a pale yellow color, a faint odor, and a weakly astringent taste. As the blossoms are visited by the honey-bee, the herb is best gathered after flowering.

The nutritive value of wood, W. RASCH (*Ztschr. Gesam. Getreidew.*, 7 (1915), No. 5, pp. 130-135).—Comparative analytical data are given regarding beech and birch wood, and rye, wheat, and oat straw. The possibility of their use as food is also discussed somewhat at length.

Hydrocyanic acid from haricot beans, H. BLAIR (*Pharm. Jour. [London]*, 4, ser., 40 (1915), No. 2689, p. 586).—The presence of hydrocyanic acid in haricot beans was detected from the odor evident upon opening a covered pan in which the beans had been steeped overnight. Laboratory tests, in which 1 gm. of ground beans was macerated in water at 45° C. and the acid washed out by a current of hydrogen and absorbed in potassium hydroxid solution, showed for periods of 27, 49, 87, 117, 198, and 358 minutes 0.025, 0.050, 0.080, 0.100, 0.120, and 0.160 mg. of hydrocyanic acid, respectively.

Botulism, an experimental study, E. C. DICKSON (*Jour. Amer. Med. Assoc.*, 65 (1915), No. 6, pp. 492-496, figs. 2).—This is a preliminary report of a laboratory investigation which was suggested by an epidemic of botulism apparently caused by eating home-canned string beans. It was desired to determine experimentally whether a medium containing animal protein is necessary for the growth of *Bacillus botulinus* and the development of its toxin (as is generally believed), and in addition to obtain more information regarding the lesions produced in the body by the toxin. Although botulism is generally spoken of as a type of meat poisoning, the author cites a number of cases of this disease which were caused apparently by eating spoiled vegetables or fruits.

To determine whether the toxin of *B. botulinus* would be developed in a vegetable medium, about 1 cc. of a suspension of the organism in normal salt solution was injected into a number of cans of high-grade commercial string beans. The cans were then resealed and allowed to incubate at room temperature for periods varying from 3 to 12 months. After incubation of the cans, aerobic and anaerobic cultures of their contents were made on various media and portions of the fluid contents were injected into laboratory animals (guinea pigs, rabbits, and cats). Pure cultures of *B. botulinus* were obtained from 6

of the 12 cans of beans inoculated. Of the 45 animals injected with the contents of the cans, 16 died and a number of others showed symptoms of botulism. Infusions of canned string beans, canned peas, pork, and beef were also inoculated with the same strain of *B. botulinus* and with another strain as a control and all incubated at 22 to 28° C. Inoculations of other animals were made from these infusions and, although all the data of this series are not complete, 22 of the animals inoculated died.

It is pointed out that since *B. botulinus* is an anaerobic organism which develops and produces its toxin best in the dark and at a temperature of 22 to 28°, canned goods afford a favorable medium for its growth. In view of the results of these experiments and the fact that spores of *B. botulinus* withstand a temperature of 85° for nearly a half hour, the author emphasizes the fact that great pains should be taken to secure the sterilization of canned fruits and vegetables, as well as meats. This is especially true in home canning, as in commercial canning practice the high temperatures and times employed in processing are generally sufficient to kill these spores.

The general conclusions drawn from the investigation are in part as follows:

“The presence of animal protein is not essential for the development of the toxin of botulism. The toxin may be produced in a medium made from string beans or from peas. An acid reaction of as much as 3.2 per cent to phenolphthalein does not prevent the formation of the toxin.”

A case of fatal poisoning by the American water hemlock (*Pub. Health Bul. [Mass.], 2 (1915), No. 2, pp. 50-52, fig. 1*).—In one case death and in another case severe illness resulted from eating the roots of this plant which is often mistaken for parsnips, artichokes, sweet cicely, horse-radish, or other edible roots. Analyses of samples of the roots showed the presence of a poison of the picrotoxin or cicutoxin group.

The harmful effect of a vegetable diet, C. VOEGLIN (*Amer. Jour. Physiol., 36 (1915), No. 4, p. 367*).—In the experiments reported laboratory animals (monkeys, white mice and rats, hogs, and cows) were given exclusive diets of natural vegetable foods. The following conclusions are drawn:

An exclusive diet of such cereals as wheat, corn, barley, oats, millet, etc., was injurious to some mammals and led eventually to death. This was also true of an exclusive diet of some fresh vegetables such as carrots, sweet potatoes, and Irish potatoes. When forming the only diet of mice and rats, legumes like beans and peas were insufficient for maintaining life. It was found that fresh beef, cow's liver, eggs, and milk, if added in sufficient quantities to vegetable food, would protect the health of the animals. It was also found that a mixed vegetable diet composed of cereals, legumes, and fresh vegetables was inadequate for maintaining the life of mice and some other animals. Fowls lived in good health and for a long time when given an exclusive diet of corn, wheat, and other cereals. The addition of certain inorganic salts to the corn resulted in prolonging the life of mice.

Some products of hydrolysis of gliadin, lactalbumin, and the protein of the rice kernel, T. B. OSBORNE, D. D. VAN SLYKE, C. S. LEAVENWORTH, and M. VINOGRAD (*Jour. Biol. Chem., 22 (1915), No. 2, pp. 259-280*).—Analytical methods are described for determining the quantity of amino acids in several proteins which form important constituents of human food.

The lysin content of gliadin was found to be 0.93 ± 0.28 per cent. The composition of lactalbumin was as follows: Lysin, 9.16 ± 0.68 per cent; histidin, 2.06 ± 0.54 per cent; arginin, 3.23 ± 0.23 per cent. Lactalbumin is exceptionally rich in lysin. “This fact is particularly interesting in view of the ability of lactalbumin to stimulate the growth of rats when used to supplement a ration low in lysin, . . .

"Compared with the endosperm proteins of wheat or maize, the protein of rice yields relatively much of each of the basic amino acids, arginin, histidin, and lysin, and comparatively little ammonia and nonamino nitrogen. In its general amino acid make-up it more nearly resembles the majority of the proteins of animal tissues than do the proteins of maize or wheat. This may explain the extensive use of rice as an almost exclusive diet in spite of its low protein content."

Protein minima for maintenance, T. B. OSBORNE, L. B. MENDEL, ET AL. (*Jour. Biol. Chem.*, 22 (1915), No. 2, pp. 241-257, fig. 1).—In continuation of previous work (E. S. R., 33, p. 262), the authors report the results of feeding experiments with laboratory animals (rats) to determine the minimum amounts of protein required for maintenance. By altering the protein content of the food—including different proportions of lactalbumin, casein, edestin, milk proteins, and gliadin in a basal ration supplying an abundance of total calories—it was possible to note how the rats actually responded to the different diets.

Additional experiments, as yet incomplete, are described in which a limited, weighed amount of food was supplied daily and eaten completely. The effect of the different proteins was studied comparatively by reducing the amount of protein in the ration until growth ceased, or a gradual decline in body weight occurred. The conclusions drawn are in part as follows:

"Ranges of 7 to 15 mg. of lactalbumin per gram of rat per week represent minima lower than those found for casein, edestin, milk proteins, or gliadin, not to mention the impossibility of maintenance with zein. . . .

"The different proteins are, with a few exceptions, not so widely divergent in their general amino acid make-up as to lead us to expect wide differences of protein minimum requirement, aside from a few striking examples. In the case of growth with its greater need of protein units, the divergencies of the proteins may manifest themselves more conspicuously than in mere maintenance. The apparently greater efficiency of lactalbumin, in contrast with the other proteins recorded above, is in harmony with the observation of the apparent economy of this protein as a supplement to deficient rations."

The need of protein under different conditions, E. ABDERHALDEN, G. EWALD, A. FODOR, and C. RÖSE (*Pflügers Arch. Physiol.*, 160 (1915), No. 9-10, pp. 511-521; *abs. in Zentbl. Physiol.*, 30 (1915), No. 4, p. 181).—Nitrogen metabolism experiments are described with diets consisting exclusively of potatoes or bread with the addition of fat or sugar. The experimental periods were of 5 to 8 days' duration. The apparent results of these tests were as follows:

With a ration of potatoes an ingestion of 4.5 gm. of nitrogen sufficed to attain a nitrogen equilibrium. The consumption of 5.9 gm. of the nitrogen supplied by a ration of Swedish bread was necessary. The amount of available nitrogen thus required was approximately 4 gm.

The metabolic relationship of the proteins to glucose.—II, Glucose formation from body proteins, N. W. JANNEY and F. A. CSONKA (*Jour. Biol. Chem.*, 22 (1915), No. 1, pp. 203-213).—The experiments here reported, which are a continuation of earlier work (E. S. R., 33, p. 261), deal with glucose originating in the metabolism of body protein with special reference to the relative amounts of glucose and nitrogen appearing in the urine of fasting diabetic laboratory animals, i. e., the G:N ratio. The results of the experimental data are summarized by the authors as follows:

"The average urinary G:N ratio in the fasting phlorizin diabetic dog is found to be 3.4:1, rather than 3.67:1. The body proteins of the dog collectively yield in metabolism about 57.5 per cent of glucose corresponding to the protein G:N ratio 3.6:1; body proteins of the rabbit about 60 per cent glucose, protein

G:N ratio 3.8:1. Body proteins of the other higher animals, including man, very probably yield nearly the same amounts of metabolic glucose as the dog and rabbit.

"The calculated yield of 45 per cent glucose, as a maximum from body protein, based on the urinary G:N ratio 2.8:1 in phlorizin and pancreas diabetes, is incorrect."

Animal calorimetry.—XII, The influence of the ingestion of fat, J. R. MURLIN, G. LUSK, and J. A. RICHE (*Jour. Biol. Chem.*, 22 (1915), No. 1, pp. 15-29, figs. 3).—The experiments reported in previous papers (*E. S. R.*, 33, p. 755) have been extended to include a study of the metabolism of laboratory animals (dogs) after the ingestion of fat alone and combined with glucose and glyco-coll. The experimental procedure was essentially the same as that described in the previous articles. The heat production of the dogs was observed after the ingestion of 75 gm. of emulsified fat, after the ingestion of 75 gm. of fat followed by 70 gm. of glucose, and after the ingestion of 50 gm. of glucose and 20 gm. of glyco-coll 4 hours after 75 gm. of emulsified fat had been eaten. The fat emulsion used consisted of 1 per cent lecithin, 37 per cent peanut oil, 37 per cent lard oil, and 25 per cent water.

These experiments showed that "the administration of fat causes a relative increase in the metabolism of fat itself. . . ."

"The increase in heat production is derived from the increased oxidation of incoming fat."

The respiratory quotient obtained in the animals to which glucose had been administered after the ingestion of fat showed that "with an ample influx of both fat and glucose at the same time, both food substances are simultaneously oxidized and with a large increase in the heat production."

It was also found that "after giving 20 gm. of glyco-coll +50 gm. of glucose during the height of the absorption of 75 gm. of fat, the increase in metabolism is nearly the sum of the increases brought about by giving each substance separately."

In summarizing the results of these experiments the authors state that the influx of fat globules into the blood stream through the thoracic duct reaches its maximum during the sixth hour after the ingestion of fat.

"The heat production of the organism may gradually rise, reach its maximum during the sixth hour, and may fall to the basal level 10 hours after fat has been ingested. It appears that the ingestion of fat does not change the quantity of heat produced from protein and glycogen, but that the increased metabolism is at the expense of the fat ingested.

"If glucose be ingested at the time of the highest fat metabolism, the heat production undergoes a second increase by the same quota which glucose alone would have increased metabolism. At this level of higher metabolism the respiratory quotient is 0.93 or 0.94, instead of unity, which it would have been if glucose had been given alone."

ANIMAL PRODUCTION.

The mechanism of Mendelian heredity, T. H. MORGAN, A. H. STURTEVANT, H. J. MULLER, and C. B. BRIDGES (*New York: Henry Holt & Co., 1915, pp. XIII+262, pl. 1, figs. 64).*—The chapters included in this book are Mendelian segregation and the chromosomes, types of Mendelian heredity, linkage, sex inheritance, the chromosomes as bearers of hereditary material, the correspondence between the distribution of the chromosomes and of the genetic factors,

multiple allelomorphs, multiple factors, and the factorial hypothesis. A bibliography relating to the literature is appended.

The fundamentals of live stock judging and selection, R. S. CURTIS (*Philadelphia: Lea & Febiger, 1915, pp. X+17-455, figs. 180*).—A general treatise on methods of live stock judging.

The value of broom millet seed compared with sorghum (*Agr. Gaz. N. S. Wales, 26 (1915), No. 8, p. 698*).—Analyses of mature sorghum seed and broom millet seed are given as moisture 12.42 and 12.71 per cent, protein 7.1 and 9.06, ether extract 3.13 and 2.6, nitrogen-free extract 71.34 and 61.84, crude fiber 3.6 and 8.53, ash 2.41 and 5.26, nutritive ratio 1:11.4 and 1:7.4, and nutritive value 85.5 and 76.7, respectively.

Report of analyses of commercial feed stuffs (*La. Dept. Agr. and Immigr. Feed Stuffs Rpt. 1913-14, pp. 152*).—Analyses made by the Louisiana State Experiment Station are reported of cotton-seed meal, rice bran, rice polish, wheat bran, shorts, middlings, screenings, corn chops, molasses feed, unbolted corn meal, hominy feed, brewers' grains, meat scrap, alfalfa meal, and various mixed and proprietary feeds.

Feeding stuffs (*Landw. Jahrb. Bayern, 4 (1914), pp. 425-436, 512-517, 534-549, 783-791*).—Analyses are given of rape seed, rape seed cake and meal, sesame cake and meal, peanut cake and meal, linseed cake and meal, sunflower seed meal, palm nut cake and meal, soy bean meal, coco cake and meal, rice feed meal, brewers' grains, malt sprouts, fish meal, blood meal, ground malt polish dust, germ oil meal, cacao shell, and turf molasses.

The starch equivalent theory, J. A. MURRAY (*Jour. Agr. Sci. [England], 7 (1915), No. 2, pp. 154-162, fig. 1*).—In this article the author points out the imperfections of the starch equivalent theory and comments upon the efforts of Wood and Yule (*E. S. R., 32, p. 166*) to correct the Kellner standard. He proposes that the feeding standards be superseded by formulas. These should be in terms of "total digestible nutrients" with given protein ratios for maintenance, growth, work, fattening, and milk production.

The maintenance ration of oxen and the starch equivalent theory, E. T. HALNAN (*Jour. Agr. Sci. [England], 7 (1915), No. 2, pp. 163-174*).—The author takes exception to the suggestions offered in the paper noted above and advocates the continued use of the Kellner system of starch equivalents. A very complete discussion is given of the development and application of the starch equivalent theory.

The mineral content of feed stuffs in relation to the weather and the mineral requirements in cattle feeding, E. KUNZE (*Mitt. Landw. Inst. Leipzig, No. 12 (1914), pp. 61-96*).—Analyses of the P_2O_5 , CaO, and K_2O contents of the grain, straw, and chaff of oats during different seasons of the year and under various methods of fertilization are reported. A résumé of literature on the subject of the effect of the mineral content of plants on the animal framework is also given.

The improvement of native cattle in Jamaica, H. H. COUSINS (*Bul. Dept. Agr. Jamaica, n. ser., 2 (1915), No. 8, pp. 338-345, pls. 10*).—It is stated that an element of zebu blood or of the Indian breeds of cattle is necessary if European breeds are to be hardened sufficiently to do well under tropical conditions in Jamaica. The Shorthorn and the Hereford have a tender white skin which is very susceptible to the influence of the tropical sun. The zebus on the other hand, even when externally light colored or white, have a black sun-resistant skin. The influence of the zebu blood is so marked that one-eighth of it is enough to give a short-haired character and a darkening of the skin to a composite animal while preserving in a marked degree the beef qualities inherent in the other introduced breed.

Caracul sheep, R. WALLACE (*Jour. Bd. Agr. [London]*, 22 (1915), No. 5, pp. 434-447, pls. 4, figs. 4).—An account of the origin, development, breed characteristics, and utility value of this breed of sheep, and of attempts in the United States and in Europe to introduce the breed.

On ovariectomy in sows, with observations on the mammary glands and the internal genital organs, IV, L. J. J. MACKENZIE and F. H. A. MARSHALL (*Jour. Agr. Sci. [England]*, 7 (1915), No. 2, pp. 243-245).—In continuation of work previously noted (E. S. R., 31, p. 870) examinations were made of the mammary pigment of four sows of colored varieties, three being Large Blacks and one a Berkshire. It was clearly proved that the dark pigment which so frequently occurs in the mammary tissue in pigs of colored breeds, and which has been found to exist even in the embryo, may be no longer present in sows which have been bred from. It is thought that the removal of this pigment takes place either during the progress of lactation or in the period of pregnancy when the mammary glands are being built up preparatory to the secretion of milk.

Harvesting crops with swine, C. E. THORNE (*Ohio Sta. Bul.* 286 (1915), pp. 244, 245).—Three lots of pigs were fed 30 days as follows: Lot 1 ear corn and clover pasture, lot 2 allowed to hog down rye, and lot 3 ear corn and rape pasture. In addition all lots were fed approximately $\frac{1}{4}$ lb. of tankage daily per pig. The respective lots made average daily gains of 0.82, 0.57, and 0.75 lb. per pig and consumed, aside from pasture, 2.66, 6.34, and 2.91 lbs. of feed per pound of gain. Lot 2 was then put in with lot 1 on clover and lot 3 remained on the rape, where the pigs were fed for 26 days. The pigs on clover made an average daily gain per pig of 0.75 lb., consuming 3.64 lbs. of feed aside from pasture per pound of gain, and the lot on clover, 0.87 lb. gain, consuming 3.16 lbs. of feed per pound of gain.

Two 3-acre plats of corn were hogged down with 33 pigs, an average daily gain of 1.76 lbs. being made. The pigs showed a return of 77 cts. per bushel, or \$36.95 per acre for the standing corn, with hogs at 7 cts. per pound and no charge for labor.

[**Report on animal husbandry work**], B. AUNE (*U. S. Dept. Agr., Bur. Plant Indus., Work Belle Fourche Expt. Farm, 1914*, pp. 6-8, fig. 1).—In experiments conducted in 1914 it was demonstrated that in pasturing alfalfa with fall and spring pigs \$11.23 per ton of alfalfa produced could be realized, whereas the market price of alfalfa hay was \$4.50 per ton. The average live weight kept on the alfalfa pasture during the season was at the rate of 1,815 lbs. per acre.

In hogging down corn, pigs increased in value in 20 days at the rate of \$40.72 per acre, bringing \$1.17 per bushel of corn consumed.

Probable error in pig feeding trials, C. CROWTHER (*Jour. Agr. Sci. [England]*, 7 (1915), No. 2, pp. 137-141).—A pig-feeding experiment is reported in which ten 8-week-old pigs were fed for 24 weeks in identically the same manner a ration consisting of bran, middlings, pea meal, and barley meal. It was found that the probable error of one pig expressed as percentage of average gain was for 3-week periods, beginning with the fourth week, as follows: Seven and five-tenths per cent, 7.9, 5.8, 7.9, 5.4, 8.4, and 5.7, and the average for the whole period was about 3.5 per cent. Attention is called to the extremely low degree of variability between the individual records and the absence of any marked tendency for the probable error (relative to increase) to fall as the feeding progressed.

These results are contrasted with those of other investigators (E. S. R., 30, p. 369), and the desirability of a closer study of the possibilities of the pig as an instrument for the measurement of small differences in nutritive value is suggested.

Missouri poultry shows and associations, T. W. QUISENBERRY and C. T. PATTERSON (*Missouri Poultry Sta. Bul.* 9 [1915], pp. 48, fig. 1).—Suggestions are given for the organization of poultry shows and associations and their management.

Egg-laying contests, M. PURVIS (*Breeder's Gaz.*, 68 (1915), No. 10, pp. 335, 336, figs. 3).—An account of recent egg-laying contests held in New South Wales and at various state experiment stations in this country.

It is said that the most important thing learned from the results of these competitions is the fact that a large egg record does not always mean the greatest profit. Often the pens which led in egg production were fourth or fifth, or even lower in rank, when the value of the eggs produced was considered. The most profitable hen lays steadily at that time in the year when eggs are most valuable. It has also been found that, all things considered, there is actually very little difference in the egg-laying ability of different breeds.

The production and handling of market eggs, T. E. QUISENBERRY (*Missouri Poultry Sta. Bul.* 5 [1915], pp. 1-69, figs. 44).—Methods of handling eggs for market are described. An article on why the egg dealer should buy on a quality basis, by H. L. Kempster, is included.

Squab raising, A. R. LEE (*U. S. Dept. Agr., Farmers' Bul.* 684 (1915), pp. 16 figs. 9).—This discusses the general management of pigeons for the production of squabs and also contains a summary of data secured from pigeon breeders throughout the United States.

DAIRY FARMING—DAIRYING.

Economic feeding for milk production in New Mexico, L. FOSTER and R. W. LATTA (*New Mexico Sta. Bul.* 98 (1915), pp. 34, figs. 5).—In trials to determine whether it pays to feed grain to cows on good pasture in New Mexico, it was found that feeding 6 lbs. of grain (bran, cotton-seed meal, and corn meal in various proportions) daily to cows on good pasture increased the milk and milk-fat production 6.5 and 9 per cent, respectively, in two experiments. In a third experiment the average grain feed was 4 lbs., and this increased the milk and milk fat only 1.5 and 2 per cent. Averaging all three experiments, the lots fed grain produced milk at a cost for feed of 0.79 cts. per pound and milk fat at a cost of 18 cts. per pound. The lots on pasture alone produced milk at a cost of 0.41 cts. per pound and milk fat at 10 cts. per pound.

In trials to determine whether it pays to feed grain in addition to first-class alfalfa hay it was found that feeding 6 to 8 lbs. of grain (corn meal and bran) per cow daily in addition to all the first-class alfalfa hay they would clean up, decreased the amount of alfalfa eaten, increased the milk and milk-fat production 12 per cent, increased the cost of milk production 25 per cent, and decreased the returns for the hay fed 20 per cent. Averaging the results of the two experiments the grain-fed cows consumed a daily average of 25.6 lbs. of alfalfa and 6.7 lbs. of grain, produced milk at 1.54 cts. per pound, and milk fat at 32.4 cts. per pound, and gained in weight 29 lbs. per month. The cows fed alfalfa alone consumed 31.2 lbs. of hay daily, produced milk at 1.195 cts. per pound and milk fat at 24.5 cts. per pound, and gained in weight 2 lbs. per month.

In a comparison of different kinds and proportions of feeds to be fed with cotton-seed meal it was found in one experiment, where 1.5 lbs. of cotton-seed meal and 1 lb. of bran per day were compared with $\frac{1}{2}$ lb. of cotton-seed meal and 3 lbs. of bran, with a basal ration of alfalfa hay and corn meal, that the ration with more cotton-seed meal and less bran produced 3 per cent more milk

at 1 per cent less cost for feed. The cows receiving the larger amount of grain ate 2.4 lbs. less alfalfa per day.

In a second experiment, cows on pasture receiving a daily grain feed of 2 lbs. of cotton-seed meal and 1 lb. of bran produced 3 per cent more milk and 5 per cent more milk fat than cows receiving only the 2 lbs. of cotton-seed meal. Several of the cows were off feed considerable of the time when fed cotton-seed meal alone, but ate their feed more regularly when fed bran with the meal. When fed cotton-seed meal alone the cows produced milk at a cost for feed, including a pasture charge of \$2.50 per month, of 0.72 ct. per pound, and milk fat at 17.5 cts. per pound. When fed 1 lb. of bran daily with the cotton-seed meal they produced milk at 0.81 ct. per pound and milk fat at 19.2 cts. per pound. Cows on the bran ration gained 235 lbs. more in body weight than when on the cotton-seed meal alone. The cows which went off feed on the cotton-seed meal alone usually lost considerable weight, as well as falling off in milk.

In a third experiment chopped alfalfa was compared with bran as a filler in a grain ration. Each mixture was fed at the rate of 1 lb. for 5 lbs. of milk. The mixture consisting of bran, cotton-seed meal, and ground Kafir corn 2:1:3, produced milk at a cost, for feed, of 0.665 ct. per pound and milk fat at 15.4 cts. per pound. The mixture consisting of alfalfa, cotton-seed meal, and ground Kafir corn 2:1:3 produced milk at 0.578 ct. and milk fat at 14.1 cts. The mixture composed of cotton-seed meal and ground Kafir corn 1:3, without any filler, produced milk at 0.635 ct. and milk fat at 16 cts.

On the bran ration the cows gained 202 lbs. in weight and on the alfalfa ration 238 lbs., while on the cotton-seed meal and Kafir corn meal alone they lost 28 lbs.

In an experiment to determine the value of silage in the ration it was found that cows fed a daily ration of 15 lbs. of alfalfa, 30 lbs. of silage, and 1 lb. of grain for each 5 lbs. of milk, produced \$121.38 worth of milk from feed costing \$69.72. Cows fed all the alfalfa they would clean up, amounting to 35 lbs. per day, and grain at the rate of 1 lb. for each 5 lbs. of milk, produced \$119.34 worth of milk from feed costing \$88.87. The silage ration produced milk at a feed cost of 0.931 ct. per pound and milk fat at 19.6 cts. per pound. The ration without silage produced milk at 1.178 cts. per pound and milk fat at 25.5 cts. per pound. Crediting all of the profit to the alfalfa used, the silage-fed cows returned \$28.32 worth of milk for each ton of alfalfa, and the cows receiving no silage, \$14.64 worth of milk for each ton of alfalfa.

Black and white Ayrshires, A. H. KUHLMAN (*Jour. Heredity*, 6 (1915), No. 7, pp. 314-322, figs. 4).—The author comments on the probable origin of the Ayrshire and its purity of breed. The black and white colors are said to be as old as the breed. A comparison of the registration in 1886 and in 1913 showed a decrease of about 10 per cent in the number of white and brown cows. In 1913 there was shown to be a remarkable similarity in the percentage of cows and bulls of the different colors, which was not the case in 1886. In 1913 there were only about one-half as many black and white cows as either red or white.

There is at present a tendency to select sires with much white. Of almost 1,000 bulls registered in volume 36 of the Ayrshire Herd Book, published in 1913, 34 per cent were brown and white, 41.93 per cent were white and brown, and 12.64 per cent had the brown restricted to the head and neck.

On the inheritance of an aural abnormality in the Ayrshire cattle, J. YAMANE (*Jour. Col. Agr. Tohoku Imp. Univ.*, 6 (1915), No. 7, pp. 163-170, pl. 1, figs. 3).—The author gives an account of the abnormal peculiarity, nicked or notched ears, frequently found in some families of the Ayrshire breed of cattle. This peculiarity is said to have originated in Scotland over 50 years ago, and

can be clearly traced in the succeeding generations. This aural abnormality is transmitted in full accord with Mendelian principles, and is a pure dominant as to the well-nicked type but heterozygous as to the slightly nicked type.

Report of committee on legislation and legal limits for the control of milk and cream, A. N. HENDERSON (*Ann. Rpt. Internat. Assoc. Dairy and Milk Insp.*, 3 (1914), pp. 85-94).—In a study of the ordinances of 32 cities of a population of 100,000 or more it was found that all these cities require certain milk fat standards, the standard varying considerably in different parts of the country. Twenty-eight of the cities require a minimum temperature standard; 18 require that milk be stored and delivered in the country at the same temperature as in the city, while 10 allow a different temperature.

A bacterial standard is specified by ordinance in 20 cities. These standards vary greatly. A separate standard in six of these cities is specified for pasteurized milk, one city specifying 100,000 and five 50,000 per cubic centimeter. Of those ordinances examined 12 require that all milk sold in the city be produced by animals free from tuberculosis, while four of the cities require that the milk sold be produced from animals free from tuberculosis or the milk pasteurized in accordance with certain regulations.

Eleven cities are regulating pasteurization by requiring certain degrees of temperature to which milk must be subjected and specifying the length of time and the degree of heat to be maintained. The period of heating in all but two ordinances is based upon a sliding scale of degrees of heat applied and length of heating period, this scale ranging from 160° F. and 2 minutes exposure to 145° and 30 minutes exposure. Of the other 2 ordinances, one requires a temperature of 145° for 20 minutes, the other of 145° for 30 minutes. Six cities require all pasteurizing apparatus to have attached a recording thermometer. Five cities require that pasteurized milk be delivered to the consumer within a specified time, one city allowing 36 hours and the remainder 24 hours within which to deliver. Eleven of the ordinances examined require all pasteurized milk to be labeled. Six cities prohibit repasteurization. One city requires that milk be put through a clarification process before pasteurization.

Six cities specify a minimum score which a farm may receive and be allowed to dispose of milk, one city requiring a 65 per cent score, three 60 per cent, one 50 per cent, and one 40 per cent. Three of the cities are using the score card adopted by the Dairy Division of the U. S. Department of Agriculture, while three are using score cards presumably arranged in part by their respective departments. Four cities specify the lowest score a milk plant may receive, three taking 70 per cent as a minimum, and one 60 per cent. Seven cities require sediment tests, and state in the ordinance the amount of sediment allowed upon a specific cotton disk. Seventeen cities prohibit the sale of dipped milk.

Eighty per cent of the ordinances in cities which have made a reduction of over 40 per cent in the last two years in the death rate from diarrhea and enteritis among children under two years of age are regarded as clear, explicit, and in conformity with advanced methods of dairy sanitation, while only 54 per cent of the ordinances of cities which have made a reduction of less than 40 per cent in the death rate are of this kind. Twenty per cent of the cities in the first group and 31 per cent of those in the second group classify their milk supply. Eighty per cent of the cities in group 1 and 50 per cent in group 2 have a bacterial standard for raw milk, the prevailing standard in group 1 being 200,000 and in group 2 500,000. Forty per cent of the cities in group 1 have a bacterial standard for pasteurized milk, and 18 per cent in group 2, the prevailing standard in both being 50,000 per cubic centimeter.

Sixty per cent of the cities in group 1 and 45 per cent in group 2 require the tuberculin testing of cows supplying milk, or that the milk shall either come from tuberculin tested animals or be pasteurized. Fifty per cent of the cities in group 1 control pasteurization by ordinance, while only 25 per cent of the cities in group 2 do so. Thirty per cent of the cities in group 1 and 4 per cent in group 2 require milk to be delivered within a specified time, the prevailing time limit in group 1 being 24 hours. Thirty per cent of the cities in group 1 and 9 per cent in group 2 prohibit repasteurization. Forty per cent of the cities in group 1 and 18 per cent in group 2 have a minimum score below which no dairy may sell milk. Eighty per cent of the cities in group 1 and 34 per cent in group 2 prohibit the sale of dipped milk.

The iron content of cow milk, F. E. NOTTBOHM and G. DÖRR (*Ztschr. Untersuch. Nahr. u. Genussmit.*, 28 (1914), No. 9, pp. 417-424).—Analytical data are given which showed the iron content of the samples tested (determined as Fe_2O_3) to be from 0.03 to 0.13 mg. per 100 cc.

The presence of *Bacillus abortus* in milk, ALICE C. EVANS (*Abs. in Science*, n. ser., 42 (1915), No. 1080, p. 352).—It has been found that the bacillus of contagious abortion occurs commonly in certified milk in the vicinity of Washington, D. C., and Chicago, Ill. The organism grows profusely on serum agar plates. About 30 per cent of the samples of milk from two certified dairies near Chicago which were plated on serum agar showed this organism to be present in milk at the time of drawing from the udder in numbers varying from 110 to 4,360 per cubic centimeter. In one sample taken from a herd which does not produce certified milk, 50,000 of the *B. abortus* were found per cubic centimeter. This organism grows abundantly in the cream layer, with the formation of acid, but sparingly in milk from which the cream has been removed. Four per cent of lactic acid in the milk does not check the multiplication of *B. abortus* in the cream layer.

A simple test for *Bacillus sporogenes* in milk and water, J. WEINZIERL (*Abs. in Science*, n. ser., 42 (1915), No. 1080, p. 353).—The sample of milk to be tested is placed in a sterile test tube, enough solid paraffin is added to make when melted a layer one-eighth of an inch in thickness, and the tubes are heated at 80° C. for ten minutes. After heating, they are cooled rapidly; this causes the melted paraffin to solidify and form a cover which effectively excludes atmospheric oxygen. The cultures are then incubated at 37° for 24 hours. If *B. sporogenes* is present, it digests the lactose and forms a gas which lifts the paraffin plug.

The test is deemed simple, cheap, and easy of application. When applied to market milk it gave the following results: Ninety samples of 5 cc. of milk each gave 28 per cent positive; 112 samples of 10 cc. of milk each gave 37.5 per cent positive; and 34 samples of 15 cc. of milk each gave 50 per cent positive.

Numbers and efficiency of *Bacillus bulgaricus* organisms in commercial preparations examined during the period January to June, 1914, RUTH C. GREATHOUSE (*Abs. in Science*, n. ser., 42 (1915), No. 1080, p. 352).—Samples of commercial preparations of *B. bulgaricus*, containing in the case of dry cultures from none to 250,000 living *B. bulgaricus* per gram, in the case of liquid cultures from 2,300 to 320,000,000 per cubic centimeter, and in the case of sour milk drinks from 800 to 790,000,000, were examined.

The maximum acidity produced in milk by the *B. bulgaricus* in these preparations varied from 1.2 to 3.41 per cent of acid, calculated as lactic. The ability of the *B. bulgaricus* to produce acid was decreased in the old preparations. The amount of decreases averaged 38.5 per cent in the case of dry cultures kept on ice for two months and 26.4 per cent in the case of liquid preparations kept on ice for two weeks.

The determination of bacteria in milk, S. H. AYERS (*Ann. Rpt. Internat. Assoc. Dairy and Milk Insp.*, 3 (1914), pp. 137-143).

Utensils as a source of bacterial contamination of milk, M. J. PRUCHA, H. A. HARDING, and H. M. WEETER (*Abs. in Science, n. ser.*, 42 (1915), No. 1080, p. 353).—In studies to determine the amount of bacterial contamination received by the milk from the utensils in which it was handled between the cow and the milk bottle, the utensils being carefully washed in the ordinary way, it was found that where all the utensils were sterile, the milk leaving the barn contained 2,588 bacteria per cubic centimeter and the bottled milk 3,875. Where the utensils were washed and only the bottles were sterile there were increases due to pails of 57,077, up to the clarifier of 15,353, due to the clarifier of 172,763, due to the cooler of 19,841, and due to the bottler 247,611.

Bottle washing costs (*Cream. and Milk Plant Mo.*, 3 (1915), No. 12, pp. 31, 32).—From visits to 91 milk plants in five cities, the Dairy Division of the U. S. Department of Agriculture found that the cost of labor of washing bottles was on the average 1.9 cts. per 100 bottles for the automatic washing, 4.9 cts. for brush washing, and 9.7 cts. for hand washing. The number of bottles washed per man per hour was 1,044, 342, and 199, and the number of bottles washed per hour 4,196, 1,061, and 433 for the respective methods.

The Grana cheese-making society, J. H. MONRAD (*N. Y. Produce Rev. and Amer. Cream.*, 40 (1915), No. 13, p. 546).—The methods of making Grana cheese prescribed by this society are given.

VETERINARY MEDICINE.

Animal experimentation and medical progress, W. W. KEEN (*Boston: Houghton Mifflin Co.*, 1914, pp. XXVI+312, figs. 12).—The author here reviews the great advance in the knowledge of diseases of domestic animals and of man and means for their prevention and cure resulting from animal experimentation.

The hygiene and diseases of live stock, P. CAGNY and R. GOVIN (*Hygiène et Maladies du Bétail. Paris: J. B. Baillière & Sons*, 1915, 2. ed., pp. 528, figs. 187).—This semipopular work deals with the hygiene and diseases of the horse, ass, mule, ox, goat, sheep, hog, and dog.

Biological therapeutics, A. EICHHORN (*Amer. Vet. Rev.*, 47 (1915), No. 2, pp. 214-224).—A succinct discussion of the topic.

A chapter in applied chemistry, A. A. BOON (*Pharm. Jour. [London]*, 4. ser., 39 (1914), No. 2670, pp. 836-838; *Jour. Soc. Chem. Indus.*, 33 (1914), No. 24, pp. 1187-1190).—A brief sketch of the manner in which the application of chemical science to the alilin-dye industry has opened up the way which led to the production of certain arsenicals, as salvarsan, of highly potent and therapeutic properties.

A study of the ninhydrin reaction in relation to the age and habits of individuals, J. TAKAMINE, JR. (*Jour. Amer. Chem. Soc.*, 37 (1915), No. 4, pp. 946-949).—Numerous tests with the blood sera of human beings and animals showed the presence of a ferment which is in direct quantitative relation to the age and habits of individuals. The procedure employed was Abderhalden's protective ferment reaction, previously noted (*E. S. R.*, 31, p. 278).

Duration of the infectiveness of virulent rinderpest blood in the water leech, *Hirudo boyn-toni*, W. H. BOYNTON (*Philippine Bur. Agr. Bul.* 29 (1914), pp. 14).—The experiments here reported have shown that the large water leech (*H. boyn-toni*) can retain the virus of rinderpest alive in its body for at least 25 days in a virulent condition. It was found that water in which leeches

have disgorged blood by mechanical stimulation or other means, after holding it for a period of five days, will cause rinderpest when drunk by a susceptible animal. Leeches which have died from mechanical or other cause after holding virulent blood for five days are able to transmit the disease when the blood is ingested by a susceptible animal. It was also found that leeches can not transmit the disease to a susceptible animal by feeding on it after they have fed upon an animal suffering from rinderpest. The trypanosome of surra does not remain alive for any length of time in the ingested blood of a leech, and the leech can not transmit the disease by biting. Thus it appears that a leech may be responsible for the appearance of recognizable rinderpest 40 days after imbibing virulent blood. In this period the leech can hold the blood 25 days, to which an incubation period of 10 days may be added.

The action of sodium sulphocyanate in tuberculosis.—XII, Studies on the biochemistry and chemotherapy of tuberculosis, H. J. CORPER (*Jour. Infect. Diseases*, 16 (1915), No. 1, pp. 38-46).—"Sodium sulphocyanate is lethal to rabbits when given intravenously in amounts of 0.4-0.6 gm. per kilogram. Delayed death may occur even from smaller amounts.

"When injected intravenously (about 0.4 gm. per kilogram), it is found in the tuberculous tissues in concentration about equal to that in the blood (0.06-0.08 per cent). The concentration in the lungs, heart, kidneys, and testes is not far from that in the blood, the concentration in the liver is less, while it is practically absent from the muscles. It disappears from the tissues (normal and tuberculous) as speedily as it does from the blood (being absent about 5 days after injection). No evidence of a chemical affinity of the sodium sulphocyanate for any of the normal or tuberculous tissues was obtained. Tubercle bacilli, exposed to concentrations of sodium sulphocyanate up to 1 per cent for 48 hours at 37° C. and up to 0.1 per cent for 7 days at 37° were not killed. No evidence even of attenuation was observed."

Sodium tellurite as a rapid test for the viability of tubercle bacilli.—XIII, Studies on the biochemistry and chemotherapy of tuberculosis, H. J. CORPER (*Jour. Infect. Diseases*, 16 (1915), No. 1, pp. 47-53).—"As a result of an attempt to use the Gossio vital reaction (sodium tellurite) as an index of life of virulent human tubercle bacilli in bactericidal experiments in connection with chemotherapeutic work, it may be stated that it was not found to be an available general reagent for this purpose, at least by the methods tested. Nevertheless, by its use a simple, rapid test was developed for determining the viability of cultures of tubercle bacilli, of value especially in eliminating such loss of time as may be occasioned by working with dead instead of viable cultures.

"A small lump of the culture to be tested is placed in the cup of a sterile, hollow glass slide and one or two small drops of sterile 0.2 per cent sodium tellurite in distilled water are added; it is covered with a sterile glass cover slip bordered with sterile vaseline and placed in the incubator at 37° C. Life of the organism is indicated by the blackening of the lump of culture, which occurs in from thirty minutes to two hours.

"Sodium tellurite is lethal to rabbits when it is given intravenously in amounts of about 0.8 mg. per kilogram. It does not kill the tubercle bacillus even when in 0.01 per cent concentration in salt solution or glycerol broth for forty-eight hours at 37° C., nor does it inhibit the growth in 0.001 per cent concentration on glycerol agar."

The tuberculin reaction in the pig, LINDNER (*Arch. K. Gsndhtsamtl.*, 48 (1914), No. 2, pp. 293-302; *abs. in Berlin. Tierärztl. Wchnschr.*, 31 (1915), No. 14, pp. 162, 163).—"The body temperature of healthy pigs two to three months old is very irregular. Generally speaking, it is said to vary between 39 and

40° C., but at times it is some tenths over this figure. From the fourth month on the temperature gets more regular. It may be between 38.7 and 39.5°, but it never goes over 40° at this time.

Healthy pigs reacted to an injection of 0.1 and 0.3 cc. of old tuberculin (in 10 cc. of physiological salt solution). In 9 out of 48 animals the rise in temperature was more than 1°, but the temperature in no case went over 41°. Sixteen 4 to 6 months' old animals were given 0.02 to 0.05 mg. of the bovine tubercle bacillus culture, and after a lapse of 4 to 8 weeks the animals received either 0.15 cc. of human tuberculin or 0.3 cc. of bovine tuberculin. The animals showed a rise in temperature of 1.1°, and the increased temperature limit vacillated between 40.6 and 42°.

Consequently, a temperature which goes over 41°, that is, a temperature of 1° over that which was observed the night previous, is to be regarded as evidence of tuberculosis in 2 to 4 months' old pigs. In older animals (with a low normal temperature) a temperature over 40.5° is considered positive.

The intracutaneous test was tried on 20 tubercular and 37 nontubercular animals. These were given 0.2 to 0.4 cc. of tuberculin in salt solution, and on the opposite flank 0.2 to 0.4 cc. of glycerol in salt solution. The reaction was positive with 15 out of 20 tubercular animals and in 1 of 37 healthy pigs. The epicutaneous test was positive with 10 tubercular pigs. The ophthalmic test was negative in 16 tubercular pigs.

An attempt to immunize calves against tuberculosis by feeding them the milk of vaccinated cows, W. L. MOSS (*Bul. Johns Hopkins Hosp.*, 26 (1915), No. 293, pp. 241-245; *abs. in Jour. Amer. Med. Assoc.*, 65 (1915), No. 4, pp. 360, 361).—The author concludes that a relative degree of immunity against tuberculosis may be conferred on calves by feeding the milk of immunized cows.

The presence of so-called "complement" in milk, R. T. HEWLETT and C. REVIS (*Jour. Hyg. [Cambridge]*, 14 (1914), No. 4, pp. 481-497; *abs. in Jour. Chem. Soc. [London]*, 108 (1915), No. 628, I, p. 70).—Milk always contains complementary substance, but this is especially true of colostrum and mastitis milks. In the latter amboceptor is also present. No relation between the amount of complementary substance and cellular elements in milk could be found. The hemolytic system is very delicate.

Warble fly experiments, S. HADWEN (*Amer. Vet. Rev.*, 47 (1915), No. 4, pp. 453-457).—The author corroborates the observations of Carpenter et al. (*E. S. R.*, 32, p. 680) in finding that the warble-fly larva penetrates the skin of its host. Mention is made of a rash or eruption which is apparently caused by the penetration of the larva, for which the term "hypodermal rash" is proposed. "The eruption begins by an escape of serum which sticks the hair together, then the patch of hair dies and can be pulled off, leaving a raw spot usually about the size of a 10-cent piece, but often larger. In other cases a little pus can be seen in the superficial layers of the skin; again in other cases, edematous swelling occur as large as one's fist, sometimes hard, sometimes soft and diffuse."

Hog cholera and the veterinarian's relation to same, F. B. WHITFIELD (*Amer. Vet. Rev.*, 47 (1915), No. 2, pp. 203-213).—After discussing the channels whereby hog cholera is disseminated, the symptoms of and the methods in vogue for preventing and curing hog cholera are considered. The dosages employed in the simultaneous method are stated.

Some observations on hog cholera and the use of serum, H. P. HOSKINS (*Amer. Vet. Rev.*, 47 (1915), Nos. 1, pp. 46-56; 2, pp. 188-196).—A discussion of mooted questions in regard to hog cholera and its treatment by the single, double, and follow-up methods. The procedure employed at the Minnesota Experiment Station is described in detail.

Inoculation experiment with pure culture of *Spirochæta hyos*: Studies on hog cholera, W. E. KING and R. H. DRAKE (*Jour. Infect. Diseases*, 16 (1915), No. 1, pp. 54-57, figs. 4).—As a continuation of previous work (E. S. R., 32, p. 378) it is now reported that some of the difficulties encountered in attempting to obtain pure culture of *S. hyos* have been overcome. By painstaking efforts a pure culture of the Spirochæta was obtained, and when injected into hogs produced typical hog cholera of the acute type.

Protective and curative vaccination tests for hog cholera with shoats, and utilizing the vaccine of Dr. Doyen of Paris, W. PFEILER (*Mitt. Ver. Deut. Schweinezüchter*, 22 (1915), Nos. 1, pp. 2-5; 2, pp. 14-16; abs. in Berlin. Tierärztl. Wchuschr., 31 (1915), No. 8, pp. 91, 92).—According to Doyen, his vaccine can be used for treating "pneumoenterite" (a disease affecting 2 to 3 months' old pigs in France), hog erysipelas, and hog cholera, as well as other infectious diseases. The vaccine was administered in laboratory tests to 8 pigs affected with hog cholera or shoat typhoid, but in no case did it alter the course of the disease, and all the animals died. In addition 54 swine of different sexes and kinds were treated in practice, and here also the results were unsatisfactory. A number (53) of the slaughtered animals showed abscesses at the site of injection.

A preliminary report on the investigation into equine abortion existing in the Province of Ontario, F. W. SCHOFIELD (*Amer. Vet. Rev.*, 47 (1915), Nos. 3, pp. 310-324; 5, pp. 547-557).—The objects of this investigation were to determine whether the abortion occurring among the mares in certain parts of Ontario is true contagious abortion, the result of an infection with a specific organism; if contagious abortion, what were the factors involved in the spreading of it from one district to another; and how the disease, when once established, can be controlled and finally eradicated.

Bacillus abortivus equinus was isolated from the uterine discharge of aborting animals. Fixation of complement occurred with *B. abortivus equinus* but not with allied strains, as *B. coli communis* or *B. cholerae suis*. In all districts where abortions have occurred the blood samples indicate that in the majority of cases they were due to *B. abortivus equinus*. Between 70 and 80 per cent of the abortions occurred during the last month of pregnancy. There were five cases in which positive fixation reactions were obtained but in which no abortions occurred.

"The agglutination and complement-fixation reactions parallel each other with great accuracy. In almost all cases of fixation the agglutination titer is high and vice versa. However, a combination of both should be employed to insure greater accuracy. In most cases where the reaction failed to show up the abortion had occurred many weeks and occasionally months previously. . . . Antibodies may still be found in the blood serum of a mare as late as seven months after the abortion.

"Investigation of the outbreaks in this Province seems to indicate that the stallion plays an important part in the spread of the disease. However, further research is necessary in order to justify any of the existing theories of natural infection."

Mixed infection vaccine in one hundred and seventy cases of joint ill, F. W. SCHOFIELD (*Amer. Vet. Rev.*, 47 (1915), No. 3, pp. 348, 349).—Bacteriological examinations were made at the Ontario Veterinary College of the synovial fluid of 23 cases of joint ill. From five, all of which occurred in an abortion-infected district, a pure culture of *Bacillus abortivus equinus* was obtained. Ten others gave an almost pure culture of a Gram positive hemolytic streptococcus, while the remaining eight were mixed infections of *B. coli*, *Staphylococcus aureus*, and *S. albus*.

"From these organisms a mixed infection vaccine was made containing approximately the following dosage per cubic centimeter: *Streptococcus* 50,000,000, *S. aureus* 100,000,000, and *B. abortivus equinus* 100,000,000. The initial dose varied from 0.5 to 1 cc. according to the age and condition of the foal. The dosage rarely produced any local and never any general reaction. The results obtained were very satisfactory."

The vaccine was distributed free to veterinarians, and a total of 170 case reports were received. The mortality in this group was 25 per cent, whereas the average mortality in the Province of Ontario is 66 per cent.

Forage poisoning in horses and mules, R. GRAHAM, L. R. HIMMELBERGER, and R. L. PONTINS (*Wallaces' Farmer*, 40 (1915), No. 36, p. 1147, figs. 4).—The authors report upon investigations conducted during the course of a serious outbreak of forage poisoning in Kentucky. Experimental animals were placed upon a farm where a total loss of \$2,000 in horses and mules that had fed on corn and oat hay had occurred. One of two horses was fed upon nothing but suspected corn, the other nothing but suspected oat hay. The horse which was fed upon oat hay contracted and died from the disease. The disease was also produced by feeding oat grain from the oat hay in question and by feeding the oat straw.

The authors state that they have been unable to transmit the disease from sick to healthy animals by blood injections, but they were able to produce it at will by feeding the oat hay.

Diseases of poultry, B. F. KAUPP (*North Carolina Sta. Bul.* 233 (1915), pp. 3-27, figs. 9).—A popular discussion in which the subject is dealt with under the headings of external parasites, internal parasites, and contagious diseases. This is followed by an account of the internal anatomy of the fowl, including a description of the proper way to open and examine the fowl after death.

RURAL ENGINEERING.

The place and field of the agricultural engineer, R. S. SHAW (*Trans. Amer. Soc. Agr. Engin.*, 8 (1914), pp. 11-18).—The author is of the opinion that the agricultural engineer should be in close cooperation with the agriculturist so that the engineering principles involved in the work of the former may be made of practical value to the latter. "Agriculture and engineering have always been interdependent, the latter paving the way for the development of the former, which in turn continues to stimulate and sustain the development of the latter."

The place and field of the agricultural engineer, A. MARSTON (*Trans. Amer. Soc. Agr. Engin.*, 8 (1914), pp. 19-26).—The author feels that in addition to the fields of salaried and consulting agricultural engineering there is a broader field for the agricultural engineer in contracting for agricultural structures and in the invention, manufacture, and sale of farm machinery and general agricultural equipment.

Surface water supply of Snake River basin, 1912 (*U. S. Geol. Survey, Water-Supply Paper* 332-B (1915), pp. 278).—This report, prepared in cooperation with the States of Idaho and Oregon, presents the results of measurements of flow made on streams in the Snake River basin in 1912.

Surface water supply of lower Columbia River and Rogue, Umpqua, Wilson, and Nehalem rivers, 1913 (*U. S. Geol. Survey Water-Supply Paper* 362-C (1915), pp. 246).—This report, prepared in cooperation with the States of Oregon and Washington, presents the results of measurements of flow made on these rivers in 1913.

Deschutes project, J. T. WHISTLER, E. G. HOPSON, and J. H. LEWIS (*Oreg. Cooper. Work, Dept. Int. U. S. Reclamation Serv.*, 1914, Dec., pp. 147, pls. 69).—

This report deals with cooperative work by the U. S. Reclamation Service and the State of Oregon, the purpose of which was to provide detailed surveys and investigations of the water resources of the State, with particular reference to irrigation and power possibilities. The report deals only with the upper Deschutes River basin.

The normal summer minimum flow of the Deschutes River at Bend is approximately 1,600 second-feet. The mean annual run-off at Benham Falls for a period of ten years is 1,210,000 acre-feet, of which approximately 20 per cent is from Crane Prairie. The area now irrigated, or to be irrigated under the Carey Act, north of Benham Falls is approximately 115,000 acres, for which there is available from the summer flow of the Deschutes River, without storage, not to exceed 450,000 acre-feet of water. In addition it is proposed to irrigate under the Carey Act about 30,000 acres of land south of Benham Falls for which storage is planned in Crescent Lake. It is stated that full irrigation development in this basin will require storage of the greater part of the entire remaining supply of over 750,000 acre-feet. Further irrigable areas considered in this investigation are a west side unit of approximately 20,000 acres north of the present State Tumalo project, with an alternative area of approximately 15,000 acres; a north unit of approximately 100,000 acres east of Deschutes River and north of Crooked River; a south unit of approximately 48,000 acres south of the present Central Oregon canal and extending north to Powell Buttes; and an east side unit of 35,000 acres, consisting of the north canal unit of the Central Oregon Irrigation Company.

The duty of water is estimated at from 2 to 2½ acre-feet per acre at the land, and the irrigation season has been estimated to be from early May to early September, with a maximum use of water during July. Storage is proposed of approximately 100,000 acre-feet in Crane Prairie and 400,000 acre-feet in Benham Falls reservoir.

A survey of the soils of the irrigable areas showed them to be generally 16 in. or more in depth. Their physical character with reference to irrigation and cultivation is generally good, but it is stated that their plant food content, particularly with reference to nitrogen, is frequently small. It is estimated that the water supply is adequate for the irrigable areas in question.

It is stated in conclusion that there is a fall in the river between Benham Falls and Bend of nearly 400 ft. available for power development in four separate falls of from 65 to 110 ft. each; that with the domestic water supply of 330 second-feet estimated, it is feasible to develop at these falls 20,000 horsepower continuously throughout the year, with a load factor of 50 per cent; and that with the full irrigation development it will be possible to develop approximately 100,000 horsepower, limited to the period of the irrigating season.

A number of maps and charts accompany the report.

Memorandum on the geology of the ground waters of the island of Antigua, British West Indies, T. W. VAUGHAN (*West Indian Bul.*, 14 (1914), No. 4, pp. 276-279).—The geology of the island with reference to the ground-water resources is outlined, and it is concluded that the geologic conditions do not satisfy the requisites for procuring an artesian water supply. It is stated that the only water-bearing formation of importance is the limestone of the limestone district. "The development of an adequate supply may be expected from three sources, viz, (1) shallow wells in the limestone district, (2) shallow wells in the alluvial fillings along stream ways and at the foot of talus slopes in the southwest volcanic district, [and] (3) impounding water, especially in the volcanic district, where it appears there are valleys adapted for damming."

The ground waters of Antigua, H. A. TEMPANY (*West Indian Bul.*, 14 (1914), No. 4, pp. 289-303, fig. 1).—This article summarizes the existing information regarding the chemical and other characteristics of waters from the various sources on the island of Antigua.

It is stated that in the limestone district there are good prospects of obtaining supplies of underground water at suitable points. "The localities at which wells are sunk should be selected with due regard to the following points: (1) They should be situated at not too great a height above sea level so as to avoid having to penetrate unnecessary thickness of rock, (2) they should be situated a sufficient distance within the limestone outcrop to insure that at the point selected the rocks to be penetrated are of adequate thickness and afford a large enough gathering ground, [and] (3) they should be situated at a sufficient distance from the sea to obviate the risk of the supply being contaminated by percolation of sea water. In addition care must be exercised in conducting boring operations to avoid passing through the limestone strata and penetrating the underlying rocks which contain the saliniferous deposits.

"In the southern district of the island there is good prospect of obtaining moderate supplies of water from wells sunk in the alluvial fillings of the valley bottoms, but in choosing sites for such wells it is advisable to avoid approaching too near to the bases of the surrounding hills. In the central plain it is inadvisable to look for a supply of water either by wells or by means of dams erected for the purpose of impounding surface flood water in the region covered by the saline deposits. To the south of this region, however, there appear to be prospects of obtaining satisfactory supplies of water by the sinking of wells, or preferably by the erection of dams."

Measurement of the flow of streams by approved forms of weirs with new formulas and diagrams, R. R. LYMAN (*Trans. Amer. Soc. Civ. Engin.*, 77 (1914), No. 1304, pp. 1189-1281, pls. 17, figs. 53).—This paper gives the details and summaries of the results of experiments by Francis, Bazin, Fteley, and Stearns, and of experiments at the hydraulic laboratories of Cornell University and the University of Utah. The purpose of the report is "to present a more accurate method of measuring water than those generally used and to give formulas and diagrams for determining the discharge over the weirs recommended."

It is the author's opinion "that the sharp-crested weir without end contractions can certainly be used to best advantage in all irrigation projects, great and small, of the West."

Formulas of the form $Q = m h^n$ were prepared for four different classes of weirs without end contractions as follows: Sharp-crested weirs, broad-crested weirs, irregular weirs with cross sections of right lines, and irregular weirs with cross sections of right lines and curves. In this formula Q designates the quantity discharged over a weir in cubic feet per second per foot of length of weir, and h designates the observed head of water on a weir in feet. The values of the constants m and n as obtained by experiment are given in tabular form.

A large amount of other related data are also given.

Stream-gaging stations and publications relating to water resources, 1885-1913, Parts XI-XII, compiled by B. D. Wood (*U. S. Geol. Survey, Water-Supply Paper 340* (1915), K, pp. XXIV+131-146; L, pp. XVIII+147-195).—These are the last two numbers of this series (*E. S. R.*, 33, p. 89). Part XI deals with Pacific coast basins in California and Part XII with the north Pacific slope drainage basins.

Experiments with the divining rod, H. METZGER (*Gsndhts. Ingen.*, 38 (1915), No. 2, pp. 13-15).—A test of the use of the divining rod for determining the location and depth of underground water supplies is described. Seven

wells were located, and the depths predicted by the operator of the diving rod varied only slightly from the actual depths to water. The operator was the only one who was able to obtain results with the rod, and while the author admits that in this case its use was not only successful but economical he expresses some doubt as to the safety of depending in general upon such means for locating water.

Investigations on the filtration of drinking water.—I, On the theory of slow sand filtration, K. KISSKALT (*Ztschr. Hyg. u. Infektionskrankh.*, 89 (1915), No. 1, pp. 57-64, fig. 1).—Experiments to determine the cause of the purifying effect of slow sand filtration on water are reported.

The results indicate that this effect can not be entirely attributed to the mechanical removal of dangerous organisms and contaminating matter by the filter and the surface scum. The use of disinfectants, such as potassium cyanid, which destroy protozoa and do not injure the bacteria almost completely destroyed the effect of a filter. It is thought, therefore, that much of the purifying effect of slow sand filtration can be attributed to the protozoa.

Sterilization of water by chlorin, J. J. H. NELSON (*Brit. Med. Jour.*, No. 2836 (1915), pp. 789-793, figs. 2).—The methods and apparatus used for the sterilization of small drinking water supplies by the use of chlorin are described and experiments with this method using artificially contaminated water and natural water are reported.

The chlorin was obtained from potassium chlorate and concentrated hydrochloric acid and was used in the experiments in the strengths of 1 part chlorin solution to about 500,000 parts water.

It was found that water artificially contaminated with *Bacillus typhosus*, *B. paratyphosus* A, and *B. cholerae* was rendered safe by this treatment after a contact of one-half hour. Natural waters were also successfully treated. The author advocates the use of the chlorin in a strength of, roughly, 1 in 500,000 parts of water and states that chlorin used in this strength does not impart any objectionable taste to the water.

This method is considered to be particularly adapted for domestic use and for camps and troops in the field. An apparatus for domestic use is described and illustrated.

Purification of drinking water by calcium hypochlorite, H. VINCENT and GAILLARD (*Compt. Rend. Acad. Sci. [Paris]*, 160 (1915), No. 15, pp. 483-486).—This article states that calcium hypochlorite is effective, rapid, and safe for the purification of drinking water. Active chlorin to the amount of 3 mg. per liter of water is considered sufficient. This may be given in a mixture of 0.015 gm. of hypochlorite of calcium and 0.08 gm. of pure sodium chlorid. The addition of the sodium chlorid, it is stated, favors the rapid diffusion and dissolution of the active chlorin in the water to be purified.

Sterilization of drinking water with chlorid of lime in the field, G. WESENBERG (*Hyg. Rundschau*, 25 (1915), No. 8, pp. 273-286, fig. 1).—Experiments on the sterilization of drinking water in the field are reported.

It was found that chlorid of lime added in a quantity corresponding to 0.15 gm. of active chlorin per liter of water is sufficient to kill infectious organisms within ten minutes. The use of increased quantities of chlorid of lime is recommended for water with a high content of contaminating organic matter, but it is considered necessary in such cases to filter the water before treatment to remove the coarsest matter. The addition of substances setting free hydrogen peroxid was found to form harmless combinations with the chlorid of lime and to remove any disagreeable taste. The composition of the water, aside from a slight increase in turbidity and hardness, was not influenced by such treatment.

In chemical studies of the fixation of chlorin by mud in water, it was found that this power differed with different mud samples, but was mainly dependent on the concentration of the chlorid of lime solution. Large increases in the amounts of chlorid of lime used only slightly increased the fixation, and in greater dilutions the same quantity of mud fixed a smaller amount of chlorin from the same quantity of chlorid of lime. The soluble parts of the mud were as active in chlorin fixation as the insoluble parts.

Practical irrigation and pumping, B. P. FLEMING (*New York: John Wiley & Sons, 1915, pp. XVI+226, figs. 62*).—This is a semitechnical treatise on irrigation pumping, it being the author's purpose "to consider the irrigation problem chiefly from the pumping standpoint, treating of those matters which interest the man considering the installation of a small pumping plant from both the standpoints of design and operation."

Beginning with estimates of the water requirements of different crops on different soils and in different localities, the author takes up in turn the matter of wells and well sinking; pumps and pumping machinery suitable for different depths and volumes, together with typical designs for certain assumed conditions; prime movers, including a discussion of oil engines, gas producers, etc.; windmill irrigation, chiefly from the standpoint of the co-relation between wind velocities and pump size; the question of cost and profit in pumping and a method of estimating the latter for certain conditions; and, finally, the central station plant and its possibilities.

Irrigation pumping in the coast States (*Elect. World, 65 (1915), No. 22, pp. 1399-1408, figs. 30*).—This article summarizes the progress made on the Pacific coast in the use of electricity for irrigation pumping.

Results of experiments with machine irrigation at the Bezenchuk and Kostychev experiment stations, I. BĚLĪĀEV (*Selsk. Khoz. i Lĕsov., 245 (1914), June, pp. 247-260, figs. 2*).—Experiments with so-called machine irrigation in arid portions of southeast Russia are reported.

Two so-called irrigation wagons were used. The first consists of a pipe 6 meters long supported by two wheels which may be moved and fastened along the pipe according to the crop to be irrigated. At each side of the pipe are branches fitted with spray nozzles. As many as fifteen such wagons may be joined into one chain. The second device consists of a four-wheeled iron wagon with the water pipe fastened onto a platform. It branches into three pipes of smaller diameter which slant upward and are connected to a horizontal pipe 14 meters long. These pipes carry five spraying nozzles which irrigate about 200 square meters (about 2,153 square feet) from one position of the machine.

At the Bezenchuk experiment station spring wheat and alfalfa were irrigated. The wheat was given 10 and 20 irrigations of 5 mm. each at intervals of 8 and 4 days, respectively. The alfalfa was given 20 and 15 irrigations of 10 and 20 mm. of water at intervals of 4 and 6 days, respectively.

At the Kostychev experiment station the crops irrigated were wheat, oats, millet, flax, and potatoes. The first three crops received 16 and 8 irrigations at intervals of 5 and 10 days, respectively, the wheat receiving 5 mm., the oats 10 mm., and the millet 10 and 5 mm. of water at an irrigation. The flax received 16 irrigations of 10 and 5 mm. at intervals of 5 days, and the potatoes 16 and 8 irrigations of 10 and 5 mm. at intervals of 5 and 10 days, respectively.

The results of the experiments were positive in all cases, but it was shown that the application of small individual amounts of water (5 mm.) gave negligible increases in crop even at frequent intervals, while larger amounts of water (10 mm.) increased the yield of oats 22 per cent and millet 21 per cent.

It is stated with reference to this method of irrigation that the manipulation of movable irrigators requires much time, care, and power. This method of so-called "rain pouring" encounters a great obstacle in the wind, it being found that to limit irrigation to nonwindy days gives poor results, while on windy days the loss of water is about 30 per cent.

Conservation of water by storage, G. F. SWAIN (*New Haven, Conn.: Yale University Press, 1915, pp. XVII+384, pls. 2, figs. 89*).—This book presents a course of lectures on water conservation by storage. The first chapter is devoted to the general subject of conservation. The next four chapters are devoted to the relation of the conservation of water to the conservation of other resources and to a somewhat lengthy discussion of the water-power question, reference being made to questions of federal control of water powers. Succeeding chapters deal with the technical aspects of water power development, the relation of forests to stream flow, and floods and their prevention.

With reference to the relation between forests and stream flow, the author is of the opinion that forests act as equalizers of the flow of streams by diminishing in general the frequency and violence of the freshets and increasing the low-water flow. "We should exercise discrimination in the utilization of our lands, cultivating for growing crops those which are best suited therefor, and reserving for forests the steep slopes and mountain sides and other areas unsuited for cultivation of crops. . . . There seems no question that forests do regulate flow, and that upon steep mountain sides especially they exercise a restraining effect upon run-off, and that they also in such locations are of inestimable benefit in preventing erosion of the soil. . . . Forests undoubtedly do something in this direction, but even if the entire country were covered with forests, it is probable that at times there would be extreme floods which would do great damage."

Hints on irrigation: Small earthen storage reservoirs, W. M. WATT (*Rhodesia Agr. Jour., 12 (1915), No. 2, pp. 172-185, fig. 1*).—The author describes reservoir and dam construction and the use of weirs under Rhodesia conditions for the benefit of irrigation farmers.

Multiple-arch diversion dam at Three Miles Falls, Oregon, H. D. NEWELL (*Engin. News, 73 (1915), No. 21, pp. 1009-1012, figs. 4*).—This article describes the construction of a long, low multiple-arch reinforced concrete dam on the Umatilla Project of the U. S. Reclamation Service.

Tour of West discloses best practice in irrigation and power canal design, C. A. FARWELL (*Engin. Rec., 71 (1915), No. 20, pp. 623, 624*).—This article reports an extended study of a number of irrigation and power projects in the West to learn costs and to determine the best practice in the design and construction of concrete linings for large canals.

It is pointed out that slopes and lining thicknesses should depend on the nature of local conditions and material encountered. Small deviations in alignment and cross section are considered immaterial. See also a previous note by Fortier (*E. S. R., 32, p. 380*).

Transmission losses in unlined irrigation channels, S. FORTIER (*Engin. News, 73 (1915), No. 22, pp. 1060-1063, figs. 3*).—The author discusses the various factors influencing seepage, referring particularly to capillarity, depth of water in the canal, velocity, sedimentation, and temperature of soil and water. He disagrees with the opinion of Moritz (*E. S. R., 30, p. 288*) that the rate of percolation of water through canal banks varies directly as the depth of water in the canal, and briefly summarizes the results of a large number of seepage measurements on canals to substantiate his argument.

Capillarity is considered to be an important factor in connection with seepage, and the gradual deposition of silt is thought to reduce seepage materially.

"The influence of velocity is relatively small. This is chiefly due to the fact that sediment can not be deposited when the mean velocity exceeds a rather low limit. Of the two factors, sedimentation and velocity, the former exerts the greater influence in lessening seepage losses, so that any increase in velocity which tends to prevent sedimentation is detrimental rather than beneficial."

A report along similar lines by the author has been previously noted (E. S. R., 32, p. 380).

How to express seepage losses from irrigation canals, S. FORTIER (*Engin. News*, 73 (1915), No. 23, pp. 1128, 1129).—The author contends that seepage losses expressed in feet-depth over the wetted area in a given time should be confined to flooded areas on irrigated fields, reservoirs, checked-up water courses, and, in general, to water surfaces where the loss can be measured directly, and not to water in motion. Instead, he advocates that seepage losses be expressed as percentage loss of flow.

In pursuing this course, it is stated that the engineer should carefully study all conditions which are likely to affect the escape of water from the canal. "These should include the amount of sedimentation per season and its effect on the character of the material, the tendency to scour under high velocities, fluctuations in depth, velocity and extent of wetted surface, inflow of seepage water from higher irrigated lands, evaporation from wet banks and water surfaces, transpiration from tree growths, leaks from structures, aquatic vegetation, the temperature of the water carried as well as that of the soil, and the location of the water table either beneath or adjacent to the canal. After a comprehensive study of existing and possible future conditions, together with all of the available data pertaining to the seepage losses from canals of like capacity traversing materials of like character as regards porosity, he will be in a position to estimate with reasonable accuracy the percentage of loss due to seepage, which may be expressed either in second-feet per mile or in percentage of the flow per mile."

Methods of plaster lining irrigation canals and laterals, Okanogan project, U. S. Reclamation Service (*Engin. and Contract.*, 43 (1915), No. 20, pp. 441-443).—This paper discusses methods of construction, cost, and efficiency of plaster lining for irrigation canals and laterals. From observations of the lining done on the Okanogan project, it is stated that the seepage loss in lined sections has been very small. The lining has cost from 5.1 to 6.4 cts. per square foot.

The use, design, construction, cost, and durability of wooden stave pipe, A. SWICKARD (*Engin. and Contract.*, 42 (1914), Nos. 19, pp. 422-424, figs. 2; 23, pp. 516-519; 43 (1915), Nos. 1, pp. 10-14, figs. 2; 7, pp. 146-148, figs. 4; 22, pp. 483-486, figs. 9).—This article, in five parts, deals with the uses and misuses, durability, design, and cost of wooden stave pipe, and with construction, organization, and methods. Considerable working data for use in design and construction are given.

Tests of submerged orifice head gates for the measurement of irrigation water, F. L. BIXBY (*New Mexico Sta. Bul.* 97 (1915), pp. 3-55, figs. 12).—This bulletin, based on work done under a cooperative agreement between the station and the Office of Experiment Stations of the U. S. Department of Agriculture, reports investigations the main purpose of which was to calibrate a submerged orifice and prepare tables for its use in measuring water for irrigation.

The submerged orifice used in the tests was an ordinary sliding head gate, the opening of which was entirely submerged. The orifice box consisted of a wooden flume 7 ft. long, 3 ft. wide, and 2.5 ft. deep, with one side so constructed as to be readily moved, thus facilitating the regulation of the width of orifice. The gate was located 2.5 ft. from the upstream end of the flume.

The orifice opening had the contraction suppressed on three sides, the bottom edge of the gate giving complete contraction.

Two sets of tests were conducted, one in which there was velocity of approach and another in which the velocity of approach was eliminated. Three hook gages were used. In the first series of tests gage G_2 was placed 1.75 ft. upstream from the plane of the orifice gate. The second gage, G_3 , was placed on the downstream side of the gate, but outside of the flume. In the second series of tests the velocity of approach was eliminated from the observation by placing a third gage, G_1 , in a stilling basin attached to the side of the flume. Three widths of opening, 1.5, 2, and 3 ft., were tested, and the height of opening varied for each width from 0.1 to 0.5 ft. From the data obtained in the first series the following standard equations were deduced for velocity of approach:

Equations for velocity of approach, series G_2-G_3 .

	Opening.	Equations as obtained.	Standard form.
1.5 ft. orifice.....	0.1 ft.	$H=1.5910 Q$ <small>$\frac{1.5992}{2.0277}$</small>	$Q=0.658A \sqrt{2gh}$ <small>$\frac{1.599}{2.0277}$</small>
Do.....	.2 ft.	$H=.3557 Q$ <small>$\frac{2.0217}{2.0217}$</small>	$Q=.712A \sqrt{2gh}$ <small>$\frac{2.0217}{2.0217}$</small>
Do.....	.3 ft.	$H=.1332 Q$ <small>$\frac{2.1638}{2.1574}$</small>	$Q=.788A \sqrt{2gh}$ <small>$\frac{2.1638}{2.1574}$</small>
Do.....	.4 ft.	$H=.0569 Q$ <small>$\frac{2.1974}{2.0100}$</small>	$Q=.916A \sqrt{2gh}$ <small>$\frac{2.1874}{2.0100}$</small>
Do.....	.5 ft.	$H=.0310 Q$ <small>$\frac{2.0100}{2.0586}$</small>	$Q=.972A \sqrt{2gh}$ <small>$\frac{2.0109}{2.0586}$</small>
2 ft. orifice.....	.1 ft.	$H=.8512 Q$ <small>$\frac{2.0586}{2.1370}$</small>	$Q=.682A \sqrt{2gh}$ <small>$\frac{2.0890}{2.1370}$</small>
Do.....	.2 ft.	$H=.1911 Q$ <small>$\frac{2.1370}{2.2900}$</small>	$Q=.733A \sqrt{2gh}$ <small>$\frac{2.0890}{2.2900}$</small>
Do.....	.3 ft.	$H=.0771 Q$ <small>$\frac{2.2900}{2.3040}$</small>	$Q=.788A \sqrt{2gh}$ <small>$\frac{2.1370}{2.2900}$</small>
Do.....	.4 ft.	$H=.0293 Q$ <small>$\frac{2.3040}{1.9875}$</small>	$Q=.947A \sqrt{2gh}$ <small>$\frac{2.2900}{1.9875}$</small>
Do.....	.5 ft.	$H=.0157 Q$ <small>$\frac{1.9875}{2.0347}$</small>	$Q=.996A \sqrt{2gh}$ <small>$\frac{2.2940}{2.0347}$</small>
3 ft. orifice.....	.1 ft.	$H=.4270 Q$ <small>$\frac{2.0347}{2.6824}$</small>	$Q=.631A \sqrt{2gh}$ <small>$\frac{1.9375}{2.0347}$</small>
Do.....	.2 ft.	$H=.0925 Q$ <small>$\frac{2.6824}{2.6824}$</small>	$Q=.694A \sqrt{2gh}$ <small>$\frac{2.0347}{2.6824}$</small>
Do.....	.3 ft.	$H=.0350 Q$	$Q=.752A \sqrt{2gh}$

From the data obtained in the second series of tests the following standard equations of flow were deduced:

Equations for no velocity of approach, series G_1-G_3 .

	Opening.	Equation as obtained.	Standard form.
1.5 ft. orifice.....	0.1 ft.	$H=1.5911 Q^2$	$Q=0.659A \sqrt{2gh}$
Do.....	.2 ft.	$H=.3630 Q^2$	$Q=.690A \sqrt{2gh}$
Do.....	.3 ft.	$H=.1412 Q^2$	$Q=.735A \sqrt{2gh}$
Do.....	.4 ft.	$H=.0715 Q^2$	$Q=.780A \sqrt{2gh}$
Do.....	.5 ft.	$H=.0434 Q^2$	$Q=.798A \sqrt{2gh}$
2 ft. orifice.....	.1 ft.	$H=.8406 Q^2$	$Q=.680A \sqrt{2gh}$
Do.....	.2 ft.	$H=.2108 Q^2$	$Q=.679A \sqrt{2gh}$
Do.....	.3 ft.	$H=.0877 Q^2$	$Q=.702A \sqrt{2gh}$
Do.....	.4 ft.	$H=.0389 Q^2$	$Q=.805A \sqrt{2gh}$
Do.....	.5 ft.	$H=.0200 Q^2$	$Q=.875A \sqrt{2gh}$
3 ft. orifice.....	.1 ft.	$H=.4260 Q^2$	$Q=.638A \sqrt{2gh}$
Do.....	.2 ft.	$H=.0948 Q^2$	$Q=.676A \sqrt{2gh}$
Do.....	.3 ft.	$H=.0380 Q^2$	$Q=.710A \sqrt{2gh}$

A value of $\sqrt{2g}=8.02$ was used in all computations. Q =discharge in cubic feet per second, h =effective head in feet, and A =area of opening in square feet.

Discharge tables for both conditions computed from these formulas are included and a working drawing with bills of materials for the submerged orifice adapted to field use is given.

"In order that the results derived from this investigation, however, be put into practical use it is necessary to follow instructions as to proper installation of the orifice head gate or erroneous results will be obtained. . . . In making a field installation the head gate must be installed in such a manner as to provide a stilling pond above the flume. This can be best accomplished by making the ditch wider at this point and the bottom of the ditch slightly below grade. The orifice flume must be leveled in both directions and it should be well puddled into place to prevent leakages along the sides of the flume and consequent washouts. Cut-off walls are placed on the upstream end of the flume and an apron placed on the downstream end to assist in preventing the undermining of the flume."

Irrigation in Nebraska, H. C. DIESEM (*Bien. Rpt. Bd. Irrig. Nebr., 10 (1913-14), pp. 24-204*).—This report deals with the present status of irrigation in Nebraska, discussing particularly the physical and financial condition of the various irrigation enterprises in the State.

Topographically the State is divided into three regions, namely, the loess, sand hill, and high plains regions. Most of the irrigation practice occurs in the high plains region. "The rainfall in the eastern half of the State is usually sufficient to produce crops and irrigation is not practiced, but in the western third or possibly half of the State, farming without irrigation is a hazardous undertaking. Generally the direct flow during the spring and early summer months of the streams located in the western part of the State greatly exceeds the demand for irrigation, but in the later summer months it rapidly diminishes and is inadequate for the acreage now under irrigation canals. . . .

"Approximately 2,000,000 acre-feet of water flow from the semiarid portions of the State each year as follows: Hat Creek 50,000, White River 100,000, Niobrara River 500,000, Plate River, less 1,070,000 acre-feet stored in Pathfinder dam, 930,000, [and] Republican River 400,000 acre-feet. . . .

"A good water supply can be obtained in all of the valleys of the different streams in the western portion of the State at depths ranging from a few feet to about 40 feet. The depth of the water is fairly uniform in each valley, but increases rapidly upon ascending the table lands, where it may be found to vary in the same locality. . . .

"There is no Carey Act project within the State, and with the exception of the Interstate Canal, built and operated by the U. S. Reclamation Service, all the canals in the State are operated under the following organizations: (1) Individual or partnership ownership, (2) mutual irrigation companies, . . . (3) stock companies, . . . [and] (4) irrigation districts."

Tenth biennial report of the state board of irrigation, highways, and drainage to the governor of Nebraska (*Bien. Rpt. Bd. Irrig. Nebr., 10 (1913-14), pp. 356, pls. 34, fig. 1*).—This report covers the operations of the board for the two years ended September 1, 1914. The section on irrigation in Nebraska, by H. C. Diesem, is noted above.

Fifth biennial report of the state engineer, J. H. LEWIS (*Bien. Rpt. State Engin. Oreg., 5 (1913-14), pp. 88, pls. 5, figs. 16*).—This report deals with the activities of the state engineer's office during the biennial period ended with November, 1914, which consisted, among other things, of water power and irrigation development.

Report of the Desert Land Board (*Bienn. Rpt. Desert Land Bd. [Oreg.], 3 (1913-14), pp. 43, figs. 11*).—This report covers the reclamation of arid lands granted to the State of Oregon under the Carey Act, and includes a brief account of the activities of the board, together with a statement of the progress and condition of each project segregated by the State.

Report of commissioner for water conservation and irrigation, L. A. B. WADE (*Rpt. Comr. Water Conserv. and Irrig. [N. S. Wates], 1913-14, pp. 188, pls. 13*).—The work and expenditures on water conservation and irrigation during the year ended June 30, 1914, are reported.

Notes on the design of drainage ditches, with diagrams, W. H. POE (*Engin. and Contract., 43 (1915), No. 20, pp. 439-441, figs. 2*).—The author outlines the method used by him in the design of open ditches and gives several related suggestions gained from personal experience.

Construction and maintenance of roads and bridges from July 1, 1913, to December 31, 1914 (*U. S. Dept. Agr. Bul. 284 (1915), pp. 64*).—This bulletin reports in detail the field work of the divisions of construction, maintenance, and national park and forest roads of the Office of Public Roads for the past fiscal year, and is a continuation of the report for the previous year (*E. S. R., 30, p. 386*).

The first section reports on the construction of sections of cement concrete, bituminous macadam, bituminous resurfaced, macadam, chert macadam, gravel, sand, clay, topsoil, and earth roads, and on the superintendence of construction of brick, gravel, earth, bituminous concrete, macadam with bituminous surface, macadam, and gravel roads. This section also includes brief reports on experimental work with limestone macadam resurfacing, post-road work, and bridge work.

The second section reports on road survey and construction work in national parks and forests done in cooperation with the Forest Service of this Department and with the Department of the Interior.

The third section reports projects for the study of the details of road maintenance as carried out by state authorities in representative States and of county maintenance in selected counties, the inauguration of maintenance of post roads constructed under the act of Congress of August 24, 1912, and the supervision of maintenance on a road from Washington, D. C., to Atlanta, Ga., in Alexandria County, Va., and on the United States experimental roads in Montgomery County, Md.

First annual report of the State Highway Commission of the State of Maine (*Ann. Rpt. Highway Com. Maine, 1913, pp. 138, pls. 13, figs. 5*).—This contains a report of the work of the commission during 1913 in addition to the ninth annual report of the commissioner of highways from January 1 to July 12, 1913.

Economical highway design, W. G. HARGER (*Engin. News, 73 (1915), No. 24, pp. 1156-1158*).—Data on the first cost and maintenance of 600 miles of New York State roads are given. Conclusions based on these data with reference to economy in highway design are as follows:

“Justifiable economy in grading is limited to the treatment of intermediate grades and to variations in cross section to fit local conditions. Economy in foundation is properly secured by a variation in design utilizing the local sources of supply with short hauls. Economy in widths of hard paving is attained by the selection of varying widths that will serve each road or part of a road satisfactorily, and by special shoulder treatment. Economy in top courses results from a selection of the minimum thickness and the type of surface that will serve satisfactorily the class of traffic to which it is subjected. Economy

of maintenance is attained by preventing damage rather than repairing damage."

Some maintenance costs, P. MACY (*Cornell Civ. Engin.*, 23 (1915), No. 8, pp. 506-512).—This article gives maintenance cost data for several types of roads in New York.

Treated wood-block paving, W. G. MITCHELL (*Dept. Int. Canada, Forestry Branch Bul.* 49 (1915), pp. 40, pls. 2, figs. 18).—This is a compilation of the information at present available from researches made in different countries in regard to the use of wood for paving. A bibliography is appended.

Concrete highways, G. W. MYERS (*Cornell Civ. Engin.*, 23 (1915), No. 8, pp. 486-492).—The author presents certain observations based upon recently acquired personal experience in the construction of concrete roads. A table giving comparative cost data on the construction and maintenance of concrete and macadam roads shows the concrete to be considerably the cheaper.

Economy of small farm gas engines, D. P. DAVIES (*Trans. Amer. Soc. Agr. Engin.*, 8 (1914), pp. 73-80, figs. 7).—Experiments with three farm internal combustion engines, rated at $1\frac{1}{2}$, 6, and 10 horsepower, with reference to fuel consumption at varying loads, are reported. All three engines were horizontal hopper-cooled, the two larger sizes being identical in design, while the smaller differed in form of combustion chamber and location and type of ignition.

It was found that all the engines developed the best fuel economy not at maximum load, but at a load approximately 67 per cent of the maximum. All the engines carried the maximum load without signs of distress. The point of greatest fuel economy coincided with the load where the governor cut out every other explosion stroke. "It is possible that this condition has a scavenging effect on every explosion stroke taking place, resulting in a higher mean effective pressure for a given amount of fuel."

Internal-combustion engine dimensions, H. L. WATSON (*Power*, 41 (1915), No. 20, pp. 672-674, fig. 1).—A chart for graphically determining the speed, bore, and stroke for a given type and size of internal-combustion engine according to American practice is given.

Electricity as a factor in progressive agriculture, E. P. EDWARDS (*Trans. N. Y. Elect. Soc.*, No 14 (1912), pp. 24, figs. 51).—The object of this paper is "to point out the possible, as well as the probable, advantages that will accrue to the farmer and the country at large through the comprehensive use of electricity by the agricultural community."

Tabular data are given of tests on electrically operated farm machines, showing, among other things, the operating cost, including interest, depreciation, and labor, with the cost of electricity at from 1 to 10 cents per kilowatt-hour.

Draft of wagons, E. B. McCORMICK (*Trans. Amer. Soc. Agr. Engin.*, 8 (1914), pp. 84-110, figs. 28; *Engin. Rec.*, 71 (1915), No. 9, pp. 265, 266).—In this article the traction dynamometer designed by the author for the Office of Public Roads of this Department is described and illustrated, and results and conclusions drawn from data obtained from its experimental use are reported.

A brief description of the instrument and its operation is as follows: The instrument is attached to a standard city dray equipped with eight sets of wheels having tires varying from $1\frac{1}{2}$ to 6 in. in width. The frame of the instrument is suspended rigidly from the bed of the wagon. Two coil springs, through which the power is transmitted, are in the line of draft from the tongue. The tongue slides freely in its guides and is attached to the traction rod of the dynamometer. As this traction rod is moved forward by the pull on the tongue, the springs are compressed an amount corresponding to the draft exerted. **This**

compression is transmitted through a rack and gear to a ribbon wheel, which through a steel ribbon, permits the record point to be moved by a coil spring which is in tension and which is attached to the other end of the guide carrying the needle point. A roll of sensitized paper 10 in. wide and some 100 yds. in length is fed through rolls which derive their motion from a sprocket wheel on the hub of one of the rear wheels. The reduction of motion is such that each inch of paper traveled represents 22 ft. of road travel, or 240 in. to the mile.

It is pointed out as a result obtained from the use of this instrument that light grades are of more importance for good hard roads than for those with a soft surface. Tests showed a greater proportional extra draft for starting a load on hard roads than on soft.

The tests from which the records shown in this article were taken gave the following drafts in pounds per ton on the different roadways: Hard dirt, 106.4; sheet asphalt, 50; block asphalt, 52; Belgian block, 47; and loose sand, 315.

With reference to the effect of tire width on the draft, the author is of the opinion "that there is a definite law by which the cumulative effect of the width of tire may be measured, and that this law is the equation of a true parabola, the constants of which vary with the road material. This variation may be sufficient to change the constants for a given width of tire to such an extent that the curve will be convex upward for one material and convex downward for the other." It was also found that the increase in draft on grades is about 20 lbs. per ton of load per cent of grade, irrespective of the road material or its condition or of the tire width.

"As the increased draft is a constant, and as the draft for the level varies with the road surface, it is evident that the importance of grade elimination depends upon the material of which the road is to be constructed. Referring to the figures previously given for drafts of a wagon on various materials, it will be seen that as 315 lbs. is necessary to haul a ton on a loose sand road, it will require a grade of over 15 per cent to double the draft; in the case of a hard dirt, a grade of over 5 per cent will be required, while in the case of sheet asphalt a grade of 2½ per cent will double the draft, while but slightly over 2 per cent is required on a road constructed of Belgian block."

Plowing investigations by the West of Scotland Agricultural College (*Impl. and Mach. Rev.*, 41 (1915), No. 481, p. 72).—The results of tests of the relative merits of the swing and digger plow, as measured by the yield of oats grown on plats plowed by the two plows, were in favor of the swing plow. It is stated, however, that on account of the dry weather the results are inconclusive. In comparing the work of the two plows, it is stated that "from an economical point of view the digger plow is far ahead of the swing."

The rotary tiller or soil milling machine, M. PATITZ (*Trans. Amer. Soc. Agr. Engin.*, 8 (1914), pp. 57-69, figs. 4).—A description is given of the mechanical details of the rotary tiller as it is being developed by manufacturing interests in this country.

Practical implements and machines for potato cultivation, STRECKER (*Maschinen Ztg.*, 13 (1915), No. 5, pp. 17-23, figs. 28).—This article describes and illustrates several types of potato planting and cultivating implements.

Experiments with steel wires, A. J. WERTH (*Mitt. Ver. Förd. Moorkultur Deut. Reiche*, 33 (1915), No. 5, pp. 76-80, figs. 2).—Experiments on Schleswig-Holstein moors showed that steel wire frames were satisfactory for beans and peas.

A comparison of the King and Rutherford systems of barn ventilation, L. J. SMITH (*Trans. Amer. Soc. Agr. Engin.*, 8 (1914), pp. 42-54, figs. 3).—The

well-known King system of barn ventilation and the so-called Rutherford system which is extensively used in the Canadian Provinces are described and compared.

In contrast to the King system, the Rutherford system allows fresh air to enter at the floor and to leave at the ceiling or roof by means of flues. "The total area of the outlet flues in the Rutherford system is made twice the total area of the intake flues. In other words, 16 or more square inches of outtake flue is allowed for each cow, and 20 or more per horse, depending on the height of the flues. Thus it is figured that a good deal of the fresh air entering the stable comes in around the doors, windows, etc. . . .

"The size of outlets is of some importance; they must be neither too small nor too large. Two to 2½ sq. ft. area is about right."

It is stated that for Canadian Northwest conditions the Rutherford system has proved superior to all others.

A plan for a small dairy house, E. KELLY and K. E. PARKS (*U. S. Dept. Agr., Farmers' Bul. 689 (1915), pp. 4, figs. 4*).—This points out briefly the requirements of a dairy house and outlines the construction and equipment of a small dairy house 20 ft. long, 10 ft. wide, 8½ ft. high in front, and 6½ ft. high in the rear. Some of the routine work of the dairy house is also briefly discussed. See also a previous article along similar lines by Webster (E. S. R., 19, p. 977).

Concrete silos (*Assoc. Amer. Portland Cement Manfrs. Bul. 21, rev. (1915), pp. 64, figs. 36*).—This pamphlet gives general information and specific structural data for use in the planning and construction of concrete silos, much of which has been compiled from bulletins of this Department and the state experiment stations.

Architectural problems of the farmhouse, W. A. ETHERTON (*Trans. Amer. Soc. Agr. Engin., 8 (1914), pp. 111-139*).—The author discusses briefly the main architectural factors making for utility, stability, and beauty in the farmhouse.

Homemade septic tank for the disposal of farm sewage, J. W. STARK (*Brampton, Ont.: Dept. Agr. Peel Co. Branch, 1915, May, pp. 8, figs. 4*).—A brief description of a small septic tank for farm use is given in this circular.

Remodeling of septic tanks into Imhoff tanks eliminates odors from land irrigation (*Engin. Rec., 71 (1915), No. 24, pp. 747, 748, figs. 3*).—A nuisance caused by the irrigation of land with septic sewage from two shallow concrete septic tanks was abated by introducing the two-story feature of the Imhoff tank by providing two wooden flowing-through chambers, thus largely preventing septic action and subsequent unpleasant odors. The difficulty seems to have been produced not so much from the odors rising directly from the tanks as from the liberated sulphureted hydrogen gases released from the septicized sewage after the latter had been spread out over the adjoining farms.

Practical cold storage, M. COOPER (*Chicago: Nickerson & Collins Co., 1914, 2. ed., pp. 802, pl. 1, figs. 273*).—This is the second edition of this work (E. S. R., 17, p. 920). It is stated in the preface that "since the appearance of the first edition . . . comparatively few improvements and changes have been made in practical applications of refrigeration, and development has been largely along the lines of perfecting and improving methods and systems already introduced. Many new applications of refrigeration have been found, and it has been demonstrated that the use of refrigeration for preventing destructive deterioration of perishable goods, so-called, as well as the controlling of chemical and other processes by supplying the low temperatures often needed, is even at the present time in its infancy."

RURAL ECONOMICS.

The rural-credits movement—danger of drifting, M. T. HERRICK (*Kansas City, Mo.: Missouri Bankers' Assoc., 1915, pp. 20*).—The author criticises the various bills bearing on rural credits that have been before Congress, and suggests that the first legislative step should be to organize land credit by requiring standard licenses and bonds of brokers and real estate agents, and by amending and enacting laws relating to credit institutions. Cooperative credit is deemed a matter for the States and Territories. The new legislation should legalize for cooperative associations everything that may now be done by a corporation, but under such regulations and restrictions as would assure safety for members and all who deal with them. The greatest care should be exercised to establish uniformity among the laws of the different States.

A practical national marketing organization and rural credits system for the United States (*Washington: Govt., 1915, pp. 16*).—In this hearing before the State Department, there was pointed out the workings of the Landwirtschaftsrat, the German national marketing organization, and the Landschaft, the German credit system, and the possibilities of their adaptation and adoption in the United States. It was argued that by means of the former a more equitable distribution of agricultural products could be obtained, through the placing of the surplus crops in localities where they are needed at the least possible cost; by means of the latter the agricultural producer would have cheap and efficient credit.

Organization of cooperative marketing associations, F. C. HART (*Ontario Dept. Agr. Bul. 234 (1915), pp. 23*).—This bulletin is intended to give detailed information as to the organization of cooperative marketing associations, and outlines the procedure from the getting together of the prospective members to the completion of the organization and the closing of the year's business.

The agricultural bank, E. FRERS (*El banco Agricola. Buenos Aires: P. Gadola, 1915, pp. 92*).—There is presented in this book the text of a proposed bill for the establishment of an agricultural bank for Argentina, with a discussion concerning the difficulties of introducing agricultural credit, the necessity for an educational propaganda, the relation of this bank to the existing credit systems, and an outline of the organization of credit under the proposed new system.

Some experiences in farm accounting, CHARLOTTE P. GODDARD (*Agr. of Mass. 62 (1914), pp. 124-141*).—The author narrates how she was employed as a cooperative bookkeeper by a number of farmers, outlines the system used, and gives sample forms.

Farm accounts simplified, D. H. OTIS (*New York: Orange Judd Co., 1915, pp. 42*).—This book contains forms for keeping farm records, in which there is an attempt to make the accounting simple by means of its mechanical arrangement.

The use of land in common in the Daun and Prum districts of Eifel, M. BERTRAM (*Landw. Jahrb., 47 (1914), No. 2, pp. 153-237*).—This study of the use of land in common indicates that forest land can be used in common to advantage, and that a common pasture is feasible where there are a number of small farmers, but that the use of other land in common is not, as a rule, satisfactory, either from a social or an agricultural point of view. A brief bibliography is included.

Overcrowding and defective housing in the rural districts, H. B. BASHORE (*New York: John Wiley & Sons, Inc., 1915, pp. 92, pls. 15*).—The author illustrates bad housing conditions as found in rural districts by calling attention

to the existence of solid blocks of houses constructed where there is plenty of land available at moderate prices; to the crowding of sleeping and living rooms to avoid extra expense for heating; to the lack of proper ventilation and lighting; to the lack of sanitary arrangements in connection with the rural schools; and to the occurrence of a large number of deaths in certain houses which appear to be infected with tuberculosis. The author believes that the ease with which pure air and sunshine can be admitted to the rural home should prevent much of the sickness and many of the deaths now occurring in rural communities.

[Trade in agricultural products] (*Ann. Rpt. Chamber Com. N. Y.*, 57 (1914-15), pt. 2, pp. 5-85).—Among the special reports given in this volume are those relating to the trade in sugar, molasses, coffee, tea, wine and spirits, cotton, tobacco, butter, cheese, and eggs, showing the trade movement, sources of supply, consumption, and prices.

California resources and possibilities (*Ann. Rpt. Cal. Develop. Bd.*, 25 (1914), pp. 64, pl. 1, figs. 9).—This report describes the industries of California and gives a large number of statistical tables indicating their importance.

Returns of produce of crops in England and Wales (*Bd. Agr. and Fisheries [London], Agr. Statist.*, 49 (1914), No. 2, pp. 121-184).—Statistical data are given showing the total production, acreage, and average yields of the principal crops by divisions and counties, together with a brief summary of the weather conditions, duration of harvest, weight of grain per bushel, and comparisons of total harvest with previous years.

Acreage and live stock returns of Scotland (*Agr. Statist. Scotland* 3 (1914), pt. 1, pp. 102).—This report gives for 1913 and 1914 the acreage of the principal crops and the number of live stock for Scotland by counties and districts, and for England, Scotland, Wales, and Ireland as a whole. The number of holdings by sizes is given by counties for 1895, 1905, 1913, and 1914.

Among the striking changes taking place in the number of live stock in 1914 are the decrease in the number of horses used for agricultural purposes by 1.81 per cent, while the unbroken and other horses increased 3.42 and 28.4 per cent, respectively. Among the cattle there was an increase in the number of cows and heifers in milk and in calf and the number under one year of age, while the number of other cattle decreased. The number of sheep kept for breeding purposes, under one year of age, increased, while the number of sheep one year of age or more decreased. The number of swine of all classes increased.

The data would seem to show an increased tendency in Scotland to develop the live-stock industry.

Returns of produce of crops in Scotland (*Agr. Statist. Scotland*, 3 (1914), pt. 2, pp. 107-180, figs. 2).—Data are given showing for Scotland, by counties and districts, the acreage, yield per acre, and total production for the principal agricultural products for 1914, and for Scotland, England, Wales, and Ireland as a whole for 1913-14. The monthly rainfall, mean temperature, and the daily duration of bright sunshine are also given.

Return of prices of crops, live stock, and other Irish agricultural products (*Dept. Agr. and Tech. Instr. Ireland, Agr. Statist. 1914*, pp. 81, pls. 16, fig. 1).—Prices of the principal crops, live stock, meat, butter, eggs, and wool at the principal market centers are given. The annual averages are given from 1895 to 1914, the monthly average price for 1913-14, the annual highest and lowest price from 1895 to 1914, and the weekly average price for 1914.

[Agricultural statistics for the Netherlands] (*Jaarc. Konink. Nederlanden, Rijk Europa 1913*, pp. 189-205).—These pages continue information previously noted (*E. S. It.*, 31, p. 391), adding data for 1913.

The agricultural industry in Russia (*Selsko-Khoziaistvennui Promysel v Rossii. Petrograd: Dept. Agr., 1914, pp. [352], pls. 7, figs. 234*).—This book contains a description of the population, soil, methods of cultivation, crops raised, and agricultural instruction and experimentation in Russia. The description is amplified by a large number of graphic representations.

A statement of the general agricultural conditions in Algeria for the crop year 1913-14 (*Bul. Agr. Algérie, Tunisie, Maroc, 21 (1915), No. 6, pp. 133-157*).—A summary is given of the general crop conditions, the extent of the harvest, the foreign trade in the principal agricultural products, the condition of agricultural credit and cooperative associations, and experiments demonstrations, and regulations tending toward the improvement of agricultural conditions in Algeria.

Live stock and agriculture (*Census Union So. Africa, 1911, pt. 9, pp. 1208-1363*).—This part of the 1911 Census of the Union of South Africa gives returns regarding live stock, agriculture, and irrigation.

It was found that there were 5,796,949 head of cattle, of which 1,620,376 were oxen; 719,444 horses; 430,641 mules and asses; 746,736 ostriches; 30,656,659 sheep; 11,763,979 goats; 1,081,600 pigs; and 10,533,909 poultry.

The land under cultivation was 3,282,971 morgen (about 7,124,047 acres), that lying fallow 892,929, and that used for grazing 89,945,238, and of the above, 34,132,230 morgen were fenced in. Additional data are given concerning the extent of irrigation, production of various crops, the number of workers, and the different types of agricultural machines and implements used.

British India, with notes on Ceylon, Afghanistan, and Tibet, H. D. BAKER ET AL. (*U. S. Dept. Com., Spec. Cons. Rpts., No. 72 (1915), pp. 318-408, figs. 2*).—Among the subjects treated in this report are acreage and production of the principal crops; production and trade in dairy products, vegetable oils, fruits, nuts, and forest products; trade customs and conditions; and irrigation methods.

AGRICULTURAL EDUCATION.

The relation of the college curriculum to human life and work, A. C. TRUE (*Educational Mo. [Ga.], 1 (1915), No. 5, pp. 157-162; Better Schools, 1 (1915), No. 8, pp. 132-135*).—The author pleads for a broader consideration of the industrial element, i. e., agriculture and mechanic arts, commerce, and household arts, in the educational system of this country from the primary school to the university, not for vocational purpose but for general or cultural education. He suggests that the general college curriculum "be perfected not so much by the addition of subjects to give the student a broader range of choice as by the reorganization and redirecting of a limited number of fundamental subjects to make him a well-educated man prepared to live in the day of his own generation."

See also a previous note (E. S. R., 32, p. 799).

The importance of agricultural education to the Commonwealth, H. PYE (*Rpt. Austral. Assoc. Adv. Sci., 14 (1913), pp. 675-694*).—In this address the author discusses the importance of agricultural education to the social, economic, and political welfare of the people of Australia, the metamorphoses and education of the farmer, the itinerant school of agriculture, the contrast between American and Australian conditions, the existing scheme of agricultural education in Australia, the functions of the elementary school and the agricultural high school, the linking of the work of the latter with that of the agricultural college, the mission of the agricultural college and the university school of agriculture, the scope and organization of the degree course in agriculture,

the importance of physics and forestry in agriculture, and the commercial and economic aspect of agriculture. It is his belief that the education of agricultural students should not be wholly concerned with the material side of life if the agricultural community is to develop great leaders to represent it in the councils of the Commonwealth and to support it in a policy of development, and that with cooperation the farming community becomes a vital force. Hence, the university, if it is to carry out its mission, should insist that the men who are to become leaders of agricultural thought should have a knowledge of life as well as be practical, scientific agriculturists.

Memorandum on the curricula of ruralized secondary schools, W. N. BRUCE (*Bd. Ed. [London] Circ. 883 (1914), pp. 21*).—The nature, organization, and content of a ruralized curriculum, together with the place of agriculture therein and outdoor work and the use of land are discussed.

It is held that the curriculum should be given a rural bias without attempting to make it purely agricultural or of emphasizing the vocational trend too strongly, and thus provide for the needs not only of those who intend to pursue rural industries, but also of the majority of those who do not. Agricultural and horticultural application of scientific principles should receive attention and be freely introduced, not with the object of teaching agriculture but of illustrating biological, chemical, and physical principles. Such technical subjects as farm implements and buildings, cultivation of various farm crops, breeds and management of live stock, etc., should be excluded as the time does not permit of their treatment concurrently with the necessary study of the fundamental sciences, their introduction will generally indicate a wrong attitude on the part of the teacher toward the course as a whole, and these subjects will not be so treated as to be of any great educational value.

The provision of a small plat of land is found highly desirable and should be used for the practical teaching of biology, chemistry, and physics through the cultivation of the soil and the growth of farm and garden plants. It should be divided into nature study plats to provide material for nature study lessons in the lower grades, a demonstration and experiment plat, a fruit plat, and separate plats of about 30 square yards for each boy of at least one of the forms, the boys doing all of the required work under the supervision of the teacher.

The training of teachers should include some practical acquaintance with the ordinary operations of a garden and a farm but need not include formal instruction in the theory and practice of agriculture as taught in the agricultural colleges.

Elementary school education as affecting the rural life problem, MABEL CARNEY (*Ann. Rpt. Conn. Bd. Agr., 46 (1913), pp. 130-142*).—In telling about her own work in the rural schools of Illinois the author indicates that the rural school is the best agency in building up community life.

Educational development in agriculture, L. S. HAWKINS (*Science Concpectus, 5 (1915), No. 2, pp. 37-41, pl. 1, figs. 4*).—This is a brief survey of what is being done by the agricultural colleges and experiment stations, extension agencies, the U. S. Department of Agriculture, and the public schools to educate the farmer.

Present requirements in the United States in instruction in nature study and elementary agriculture, E. R. DOWNING (*Nature-Study Rev., 11 (1915), No. 6, pp. 297-299*).—This is a tabulation of requirements in nature study and elementary agriculture in the graded schools of the several States and Territories.

Agriculture in the schools of Mansfield and Lebanon, A. J. BRUNDAGE (*Ann. Rpt. Conn. Bd. Agr., 46 (1913), pp. 77-80*).—This is a brief report on an

experiment in requiring instruction in agriculture in the public schools of Mansfield and Lebanon, Conn. The children above the fourth grade are taken into one class for the four-year agricultural work, directed by an agricultural supervisor. About 80 per cent of the children taking agriculture in the schools carry on some directed home work, and corn, potato, garden and canning, poultry, and dairy clubs have been organized. Some of the benefits of the home work are pointed out.

What the public schools of Indiana are doing in pre-vocational agricultural work (*Dept. Pub. Instr. [Ind.], Ed. Pubs., Bul. 16 (1915), pp. 30, figs. 17*).—This is a report on the agricultural work that has been done by the public schools in general throughout the State, and on home problem work in several different communities, and its value, continuation work during the summer, agricultural teachers in Indiana, helps from the state department of public instruction, county agricultural agents, short courses and demonstrations, colleges and normal schools, and the Purdue University department of education.

Vocational agriculture, G. A. WORKS (*Agr. Student, 22 (1915), No. 1, pp. 49-52, fig. 1*).—The author describes the vocational agricultural instruction in the high schools of the State of New York, including individual and group project work.

Domestic science in the schools (*Agr. Gaz. Canada, 2 (1915), No. 4, pp. 362-371*).—Brief reports are given on the present status of instruction in domestic science in the public schools of Nova Scotia, New Brunswick, Quebec, Ontario, Manitoba, Saskatchewan, Alberta, and British Columbia.

Credit for home work, E. B. WHALEY (*Proc. W. Va. Ed. Assoc., 44 (1914), pp. 101-108*).—This paper discusses credit for home work as it bears upon (1) the broadening of the curriculum so as to give every pupil a chance to discover his capacities, (2) the adaptation of the rural school to the community, and (3) a more vital cooperation between the school and the home. In connection with this paper the author submits the report of a committee on credit for home work which recommends that the farm home be made the laboratory of the rural schools, and suggests lists of laboratory work in agriculture, hygiene, manual training, and domestic science from which the required amount of work might be chosen.

The model school garden (*Agr. Gaz. Canada, 2 (1915), No. 3, pp. 268-283, figs. 8*).—This symposium comprises (1) a suggested diagram and planting plan of a school garden prepared by L. A. DeWolfe, director of elementary agricultural education for Nova Scotia; (2) a diagram of a school garden with suggestions on selection of site, size, fall preparation of soil, planning and cultivation of garden, by R. P. Steeves, director of elementary agricultural education of New Brunswick; (3) a brief account of the progress of schools gardens in Quebec, by J. A. Grenier, secretary of the Quebec Department of Agriculture; (4) a discussion of the meaning of school gardening, the relation of nature study and elementary agriculture, and of the chief features of the ideal school garden aimed at for Ontario schools, by S. B. McCready, director of elementary agricultural education of Ontario; (5) a brief statement of the nature and scope of gardening possible in a school, by H. W. Watson, director of elementary agricultural education of Manitoba; and (6) the essentials both as to the purposes or educational value of the school garden and as to the make up of the garden itself and how many of these features might reasonably be included in one garden, by J. W. Gibson, director of elementary agricultural education of British Columbia.

Why school gardens fail (*Agr. Gaz. Canada, 2 (1915), No. 7, pp. 682-686*).—Among the reasons given in this series of articles by educational authorities

in the Provinces of Nova Scotia, Quebec, Saskatchewan, and British Columbia for the failure of school gardens are the following: The too frequent change of teachers; an attempt to undertake too much; the lack in teachers of preparation, enthusiasm, power of leadership, and understanding of the object of the school garden; the lack of cooperation between teachers and between trustees and teachers; the lack of care during the summer vacation; and the unsuitability of school grounds, either on account of condition or size, etc.

Boys' and girls' clubs, R. H. EMBERSON and G. W. REAVIS (*Mo. Col. Agr., Agr. Ext. Serv. Proj. Announcement 3 (1915), pp. 24, figs. 8*).—This bulletin gives directions for organizing boys' and girls' clubs, lesson topics, and contests for corn, poultry, sewing, stock judging, pig, tomato, bread, and canning clubs. A list of Farmers' Bulletins of this Department classified according to the different club projects is included.

Boys' and girls' club work in New Mexico, W. T. CONWAY and DORA E. ROSS (*N. Mex. Col. Agr., Ext. Div. Bul. 1 (1915), pp. 24*).—The authors outline the purpose and plan of work of boys' and girls' clubs in New Mexico.

Boys' and girls' industrial clubs of Oregon, E. F. CARLETON (*[Salem, Oreg.]: Dept. Ed., 1915, pp. 7, figs. 3*).—A brief survey is given of the organization of industrial club work of the boys and girls of Oregon conducted by the state department of education in cooperation with the Oregon Agricultural College and this Department. A list of 12 club projects which have been undertaken to adapt the work to the needs of different sections of the State is included.

Industrial club work of Oregon boys and girls, N. C. MARIS and L. P. HARRINGTON (*Salem, Oreg.: Dept. Ed., 1915, pp. 42, figs. 32*).—The authors give a review of the work of the past year, including stories and club project reports by some of the club members.

Organization of boys' pig clubs, W. H. BALIS (*La. Agr. Col., Ext. Div. Circ. 2 (1915), pp. 8, figs. 6*).—Directions are given for organizing and conducting boys' pig clubs in Louisiana.

The farm in the work of the primary grades, GRACE RAIT (*Atlantic Ed. Jour., 10 (1915), No. 10, pp. 15, 16*).—The author outlines work for the first grade based on the farm as a source of motive.

Soils and plant life as related to agriculture, J. C. CUNNINGHAM and W. H. LANCELOT (*New York: The Macmillan Co., 1915, pp. XX+348, pl. 1, figs. 154*).—The authors present a first study in agriculture dealing with soils and plants, including field, fruit, and vegetable crops, for rural, graded, and high schools. The text is interspersed with practical exercises and review questions, and lists of equipment and publications are added.

A course of practical work in the chemistry of the garden, D. R. EDWARDS-KER (*London: John Murray, 1914, pp. 40*).—This course for teachers and students of horticulture, gardening, and rural science consists of experiments in the chemistry of plants, soils, manures and fertilizers, and sprays and washes. An appendix gives directions for the preparation of solutions mentioned in the text.

Corn: A guide for judging varieties adapted to Oklahoma conditions, A. DAANE and F. F. FERGUSON (*Okla. Agr. Col., Ext. Div. Circ. 16 (1915), pp. 13, figs. 4*).—This guide adopts variety standards comprising five groups, and gives descriptions of the varieties, rules for judging corn exhibits, directions for special seed selection and growing seed corn, and suggestions on plant qualifications in ear selection.

Seed corn testing, E. HOPT and F. D. KEIM (*Nebr. Col. Agr., Ext. Serv. Lesson 3, pp. 4, figs. 4*).—Directions for making a general test and individual ear test of corn are given.

Laboratory manual of horticulture, G. W. HOOD (*Boston and London: Ginn & Co., 1915, pp. VI+234, figs. 52*).—The 78 exercises in this manual consist of studies of seeds, bulbs, corms, cuttings, buds, pruning, grafting and grafting waxes, fungicides and insecticides, and the apple, grape, peach, pear, and plum. Their aim is to assist the student in grasping some of the fundamental principles of horticulture and in learning by actual experimentation and observation the reasons for certain necessary horticultural operations. Blank pages for the student's notes and report are included, as well as a glossary of descriptive terms. These exercises have been given in connection with the work in general horticulture at the Ohio State University, Michigan Agricultural College, and the University of Nebraska.

A vegetable gardening syllabus for teachers, ETHEL GOWANS (*U. S. Bur. Ed. [Syllabus], 1915, Apr., pp. 4*).—An outline is given of field and classroom work in vegetable gardening, the latter consisting of projects on the requirements for plant growth, management of the soil, and selection of seeds.

The principles of floriculture, E. A. WHITE (*New York: The Macmillan Co., 1915, pp. XX+467, pl. 1, figs. 52*).—This book, which is an outgrowth of the author's experience and observations, has been prepared to meet the need for a classroom text on the principles that underlie the successful culture of ornamental plants. It treats of the importance and development of the flower industry in the United States and Canada; centers of the industry and the markets; factors which influence the selection of a location; glass structures and their arrangement, construction, heating, and management; plant structure and its relation to healthy plant growth; reproduction; soil for and diseases and insect pests of greenhouse plants; cut flower crops, potted flowering and fruiting plants, foliage plants, hardy plants and their adaptation for forcing, plants for outdoor bedding, window and veranda boxes, and packing and shipping plants and flowers.

Judging dairy cattle, G. GUSLER (*Agr. Col. Ext. Bul. [Ohio State Univ.], 10 (1915), No. 10, pp. 23, figs. 15*).—Directions are given for judging dairy cattle.

Milk and milk products in the home, J. MICHELS (*Farmingdale, N. Y.: Author, 1915, pp. 100, pl. 1, figs. 19*).—This text for students in home economics and housekeepers in general treats of the composition, physical properties, and food value of milk and its products, the care of milk in the home, market classes of milk, and the production of clean wholesome milk, including a score card on equipment and method.

Farm-business arithmetic, C. J. LEWIS (*Boston: D. C. Heath & Co., 1915, pp. XIII+199, pl. 1, figs. 2*).—This book of farm problems may be used as a course of daily lessons or as supplementary arithmetic work. Many of the subjects can be mastered by pupils between the ages of 12 and 15 years. Problems are given in farm accounting and business forms, farm and market values, harvesting, shipping, poultry keeping, dairying, farm feeding, planting, farm occupations, the business end of farm life, farm management, etc.

Agricultural collections for school laboratories (*Mo. Col. Agr., Agr. Ext. Serv. Proj. Announcement 2 (1915), pp. 29*).—The laboratory material listed in this bulletin has been prepared especially for the use of high schools in teaching field crops, horticulture, entomology, and soils and fertilizers. The collections, which can be used also in the home or graded rural schools, may be procured from the agricultural extension service of the University of Missouri at a nominal cost.

NOTES.

Arizona University and Station.—The new agricultural building has just been completed at a cost of \$165,000. This building contains the offices of the president and business manager of the university, the dean and director of the college of agriculture and station, and the departments of agronomy, horticulture, animal husbandry, agricultural chemistry, plant breeding, home economics, agricultural extension, and archaeology.

P. W. Moore has been appointed fellow in agricultural chemistry and T. E. Schreiner, of Cornell University, to take charge of the poultry work.

Arkansas University and Station.—J. B. Rather, formerly of the Texas Station, has been appointed head of the department of agricultural chemistry in the university and station, with E. G. Will as assistant. H. E. Truax has resigned to accept a position with the States Relations Service of this Department in its studies of agricultural instruction and has been succeeded as assistant in horticulture by C. H. Hurd. F. H. Herzer has been appointed assistant in animal husbandry for special work in dairying, and Ruth A. Peck, head of the department of home economics to succeed Miss Sarah Pettit.

Kentucky Station.—D. D. Slade, superintendent of the poultry farm, has been transferred to extension work. N. R. Elliott has been appointed assistant in horticulture, and D. H. Wilkins, research assistant in poultry, beginning September 1.

Mississippi Station.—H. K. Gayle, a county agent in Kentucky, has been appointed animal husbandman.

New Jersey College and Stations.—Recent appointments include the following: Lloyd S. Riford, assistant dairy husbandman and instructor in dairy husbandry, vice A. S. Cook, resigned; Roy F. Irvin, instructor in poultry husbandry, vice C. E. Brett, resigned; Dr. John W. Shive, plant pathologist; J. Marshall Hunter, inspector for the Live Stock Commission; Carl R. Woodward, librarian and editor; William S. Porte, assistant in plant breeding; Orville C. Schultz, assistant in plant physiology; S. A. Waksman and Roland E. Curtis, assistants in soil fertility; William H. Martin, assistant in plant pathology, vice George W. Martin, resigned; W. S. Krout, assistant in plant pathology; A. C. Foster, seed analyst, vice Robert W. Schmidt, resigned; and Homer C. Carney, assistant seed analyst.

John H. Voorhees and Charles M. Arthur, extension specialists in agronomy and market methods respectively, have resigned, the latter to become instructor in agricultural extension in the Pennsylvania College.

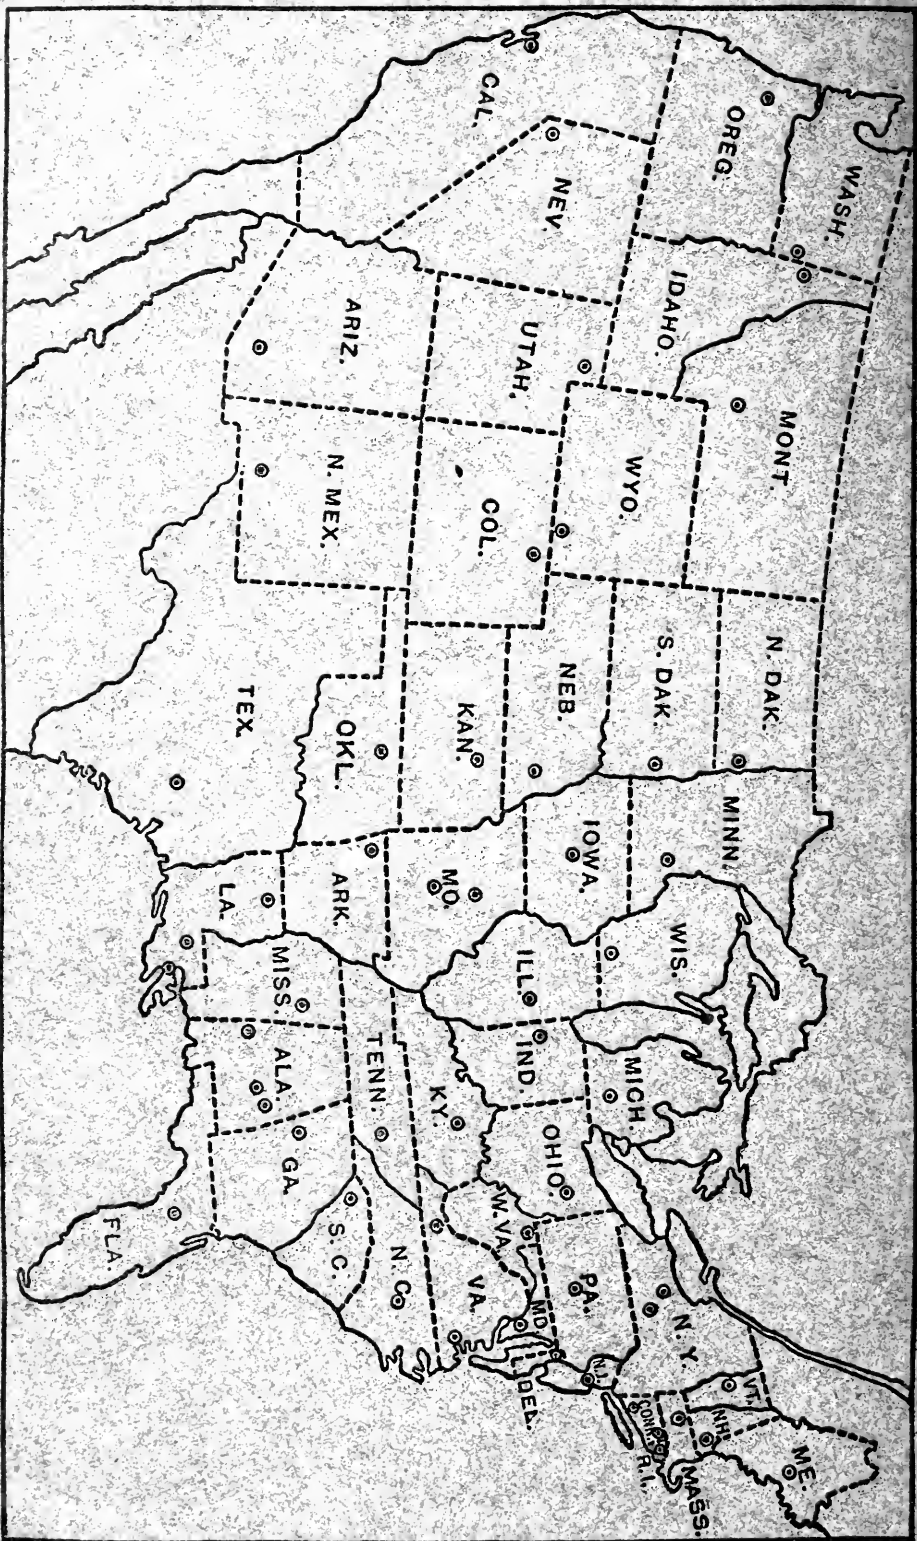

Pennsylvania Institute of Animal Nutrition.—J. E. Mensching, J. E. Isenberg, and E. W. Schmidt have been appointed assistants in animal nutrition. F. C. Dosé has resigned.

Porto Rico College and Station.—Samuel D. Gray has been appointed professor of entomology in the college, vice R. I. Smith, who has assumed charge of the Boston office for the foreign cotton quarantine against the pink boll worm of Egypt and other countries. Policarpio González has been appointed assistant in agriculture. His work will include the instruction of rural teachers in agriculture.

Elmer W. Brandes has been appointed plant pathologist in the station.

Washington Station.—Dr. J. S. Caldwell, botanist of the Alabama College and Station, has been appointed in charge of the fruit by-products investigations.

THE AGRICULTURAL EXPERIMENT STATIONS.

ALABAMA—

College Station: *Auburn*; J. F. Duggar.^a
 Canebrake Station: *Uniontown*; L. H. Moore.^a
 Tuskegee Station: *Tuskegee Institute*; G. W. Carver.^a

ALASKA—*Sitka*: C. C. Georgeson.^b

ARIZONA—*Tucson*: G. F. Freeman.^c

ARKANSAS—*Fayetteville*: M. Nelson.^a

CALIFORNIA—*Berkeley*: T. F. Hunt.^a

COLORADO—*Fort Collins*: C. P. Gillette.^a

CONNECTICUT—

State Station: *New Haven*; } E. H. Jenkins.^a
 Storrs Station: *Storrs*; }

DELAWARE—*Newark*: H. Hayward.^a

FLORIDA—*Gainesville*: P. H. Rolfs.^a

GEORGIA—*Experiment*: R. J. H. De Loach.^a

GUAM—*Island of Guam*: A. C. Hartenbower.^b

HAWAII—

Federal Station: *Honolulu*; J. M. Westgate.^b
 Sugar Planters' Station: *Honolulu*; H. P. Agee.^a

IDAHO—*Moscow*: J. S. Jones.^a

ILLINOIS—*Urbana*: E. Davenport.^a

INDIANA—*La Fayette*: A. Goss.^a

IOWA—*Ames*: C. F. Curtiss.^a

KANSAS—*Manhattan*: W. M. Jardine.^a

KENTUCKY—*Lexington*: J. H. Kastle.^a

LOUISIANA—

State Station: *Baton Rouge*; }
 Sugar Station: *Audubon Park*; } W. R. Dodson.^a
New Orleans; }

North La. Station: *Calhoun*;

MAINE—*Orono*: C. D. Woods.^a

MARYLAND—*College Park*: H. J. Patterson.^a

MASSACHUSETTS—*Amherst*: W. P. Brooks.^a

MICHIGAN—*East Lansing*: R. S. Shaw.^a

MINNESOTA—*University Farm, St. Paul*: A. F. Woods.^a

MISSISSIPPI—*Agricultural College*: E. R. Lloyd.^a

MISSOURI—

College Station: *Columbia*; F. B. Mumford.^a
 Fruit Station: *Mountain Grove*; Paul Evans.^a

MONTANA—*Bozeman*: F. B. Linfield.^a

NEBRASKA—*Lincoln*: E. A. Burnett.^a

NEVADA—*Reno*: S. B. Doten.^a

NEW HAMPSHIRE—*Durham*: J. C. Kendall.^a

NEW JERSEY—*New Brunswick*: J. G. Lipman.^a

NEW MEXICO—*State College*: Fabian Garota.^a

NEW YORK—

State Station: *Geneva*; W. H. Jordan.^a

Cornell Station: *Ithaca*; B. T. Galloway.^a

NORTH CAROLINA—

College Station: *West Raleigh*; } B. W. Kilgore.^a
 State Station: *Raleigh*; }

NORTH DAKOTA—*Agricultural College*: T. P. Cooper.^a

OHIO—*Wooster*: C. E. Thorne.^a

OKLAHOMA—*Stillwater*: W. L. Carlyle.^a

OREGON—*Corvallis*: A. B. Cordley.^a

PENNSYLVANIA—

State College: *R. L. Watts*.^a

State College: *Institute of Animal Nutrition*;
 H. F. Armsby.^a

PORTO RICO—

Federal Station: *Mayaguez*; D. W. May.^b

Insular Station: *Rio Piedras*; W. V. Tower.^a

RHODE ISLAND—*Kingston*: B. L. Hartwell.^a

SOUTH CAROLINA—*Clemson College*: J. N. Harper.^a

SOUTH DAKOTA—*Brookings*: J. W. Wilson.^a

TENNESSEE—*Knoxville*: H. A. Morgan.^a

TEXAS—*College Station*: B. Youngblood.^a

UTAH—*Logan*: E. D. Ball.^a

VERMONT—*Burlington*: J. L. Hills.^a

VIRGINIA—

Blacksburg: W. J. Schoene.^c

Norfolk: Truck Station; T. C. Johnson.^a

WASHINGTON—*Pullman*: I. D. Cardiff.^a

WEST VIRGINIA—*Morgantown*: J. L. Coulter.^a

WISCONSIN—*Madison*: H. L. Russell.^a

WYOMING—*Laramie*: C. A. Duniway.^c

^a Director.

^b Agronomist in charge.

^c Acting director.

INDEX OF NAMES.

- Aarstad, H., 492.
 Abbe, C., 321.
 Abbe, C., Jr., 320.
 Abbey, M. J., 494, 495, 697.
 Abbot, C. G., 717.
 Abbott, J. B., 22.
